General Introduction to the TIMES Documentation

This documentation is composed of five Parts.

**Part I** provides a general description of the TIMES paradigm, with emphasis on the model’s general structure and its economic significance. Part I also includes a simplified mathematical formulation of TIMES, a chapter comparing it to the MARKAL model, pointing to similarities and differences, and chapters describing new model options.

**Part II** constitutes a comprehensive reference manual intended for the technically minded modeler or programmer looking for an in-depth understanding of the complete model details, in particular the relationship between the input data and the model mathematics, or contemplating making changes to the model’s equations. Part II includes a full description of the sets, attributes, variables, and equations of the TIMES model.

**Part III** describes the organization of the TIMES modeling environment and the GAMS control statements required to run the TIMES model. GAMS is a modeling language that translates a TIMES database into the Linear Programming matrix, and then submits this LP to an optimizer and generates the result files. Part III describes how the routines comprising the TIMES source code guide the model through compilation, execution, solve, and reporting; the files produced by the run process and their use; and the various switches that control the execution of the TIMES code according to the model instance, formulation options, and run options selected by the user. It also includes a section on identifying and resolving errors that may occur during the run process.

**Part IV** provides a step-by-step introduction to building a TIMES model in the VEDA-Front End (VEDA-FE) model management software. It first offers an orientation to the basic features of VEDA-FE, including software layout, data files and tables, and model management features. It then describes in detail twelve Demo models (available for download from the ETSAP website) that progressively introduce VEDA-TIMES principles and modeling techniques.

**Part V** describes the VEDA Back-End (VEDA-BE) software, which is widely used for analyzing results from TIMES models. It provides a complete guide to using VEDA-BE, including how to get started, import model results, create and view tables, create and modify user sets, and step through results in the model Reference Energy System. It also describes advanced features and provides suggestions for best practices.
PART II: REFERENCE MANUAL
TABLE OF CONTENTS FOR PART II

1 INTRODUCTION ........................................................................................................... 8
  1.1 Basic notation and conventions ........................................................................... 8
  1.2 GAMS modelling language and TIMES implementation ....................................... 9

2 SETS .......................................................................................................................... 10
  2.1 Indexes (One-dimensional sets) ........................................................................... 10
  2.2 User input sets ...................................................................................................... 15
    2.2.1 Definition of the Reference Energy System (RES) ............................................ 15
    2.2.1.1 Processes .................................................................................................... 16
    2.2.1.2 Commodities .............................................................................................. 20
    2.2.2 Definition of the time structure ...................................................................... 20
      2.2.2.1 Time horizon .............................................................................................. 20
      2.2.2.2 Timeslices ................................................................................................. 22
    2.2.3 Multi-regional models ..................................................................................... 24
    2.2.4 Overview of all user input sets ....................................................................... 26
  2.3 Definition of internal sets ..................................................................................... 31

3 PARAMETERS ............................................................................................................. 36
  3.1 User input parameters .......................................................................................... 36
    3.1.1 Inter- and extrapolation of user input parameters ............................................ 36
      3.1.1.1 Inter/extrapolation options ................................................................. 37
      3.1.1.2 Default inter/extrapolation ................................................................. 38
      3.1.1.3 Interpolation of cost parameters .......................................................... 38
      3.1.1.4 Examples of using I/E options ............................................................... 38
      3.1.1.5 Applicability ......................................................................................... 40
    3.1.2 Inheritance and aggregation of timesliced input parameters ............................ 41
    3.1.3 Overview of user input parameters ................................................................ 43
  3.2 Internal parameters ............................................................................................... 90
  3.3 Report parameters ............................................................................................... 98
    3.3.1 Overview of report parameters .................................................................... 98
    3.3.2 Acronyms used in cost reporting parameters .............................................. 105
    3.3.3 The levelized cost reporting option ............................................................. 105

4 USAGE NOTES ON SPECIAL TYPES OF PROCESSES ........................................ 108
  4.1 Combined heat and power .................................................................................. 108
    4.1.1 Overview ..................................................................................................... 108
    4.1.2 Defining CHP attributes in TIMES ............................................................ 109
      4.1.2.1 Back-pressure turbine systems .............................................................. 109
      4.1.2.2 Pass-out turbine systems ...................................................................... 110
      4.1.2.3 Alternative choices for defining the activity basis ................................ 111
    4.2 Inter-regional exchange processes .................................................................. 112
      4.2.1 Structure and types of endogenous trade .................................................. 112
      4.2.2 Input sets and parameters specific to trade processes ................................. 116
      4.2.3 Availability factors for trade processes ..................................................... 118
      4.2.4 Notes on other attributes for trade processes ............................................. 119
  4.3 Storage processes ............................................................................................... 120
    4.3.1 Overview ..................................................................................................... 120
    4.3.2 Timeslice storage .......................................................................................... 120
    4.3.3 Day/Night storage ....................................................................................... 121

APPENDIX A THE TIMES CLIMATE MODULE ......................................................... 313

APPENDIX B DAMAGE COST FUNCTIONS ......................................................... 341

APPENDIX C ENDOGENOUS TECHNOLOGICAL LEARNING (ETL) ............ 358
1 Introduction

The purpose of the Reference Manual is to lay out the full details of the TIMES model, including data specification, internal data structures, and mathematical formulation of the model’s Linear Program (LP) formulation, as well as the Mixed Integer Programming (MIP) formulations required by some of its options. As such, it provides the TIMES modeller/programmer with sufficiently detailed information to fully understand the nature and purpose of the data components, model equations and variables. A solid understanding of the material in this Manual is a necessary prerequisite for anyone considering making programming changes in the TIMES source code.

The Reference Manual is organized as follows:
Chapter 1 Basic notation and conventions: lays the groundwork for understanding the rest of the material in the Reference Manual;
Chapter 2 Sets: explains the meaning and role of various sets that identify how the model components are grouped according to their nature (e.g. demand devices, power plants, energy carriers, etc.) in a TIMES model;
Chapter 3 Parameters: elaborates the details related to the user-provided numerical data, as well as the internally constructed data structures, used by the model generator (and report writer) to derive the coefficients of the LP matrix (and prepare the results for analysis);
Chapter 4 Usage notes on special types of processes: Gives additional information about using input sets and parameters for the modelling of special types of processes: CHP, inter-regional exchange, and storage processes;
Chapter 5 Variables: defines each variable that may appear in the matrix, both explaining its nature and indicating how it fits into the matrix structure;
Chapter 6 Equations: states each equation in the model, both explaining its role and providing its explicit mathematical formulation. Includes user constraints that may be employed by modellers to formulate additional linear constraints, which are not part of the generic constraint set of TIMES.
Appendix A The Climate Module;
Appendix B The Damage Cost Functions, and
Appendix C The Endogenous Technological Learning capability.

1.1 Basic notation and conventions

To assist the reader, the following conventions are employed consistently throughout this chapter:

- Sets, and their associated index names, are in lower and bold case, e.g., com is the set of all commodities;
- Literals, explicitly defined in the code, are in upper case within single quotes (note that in conformity with the GAMS syntax, single quotes must, in fact, be apostrophes), e.g., 'UP' for upper bound;
- Parameters, and scalars (constants, i.e., un-indexed parameters) are in upper case, e.g., NCAP_AF for the availability factor of a technology;
- Variables are in upper case with a prefix of VAR_, e.g., VAR_ACT corresponds to the activity level of a technology.
Equations are in upper case with a prefix of EQ_ or EQ(l)_ with the placeholder (l) denoting the equation type (l=E for a strict equality, l=L for an inequality with the left hand side term being smaller than or equal to the right hand side term and l=G for an inequality with the left hand side term being greater than or equal to the right hand side term), e.g., EQ_PTRANS is the process transformation equation (strict equality), and EQG_COMBAL is the commodity balance constraint equation (strict equality).

1.2 GAMS modelling language and TIMES implementation

TIMES consists of generic variables and equations constructed from the specification of sets and parameter values depicting an energy system for each distinct region in a model. To construct a TIMES model, a preprocessor first translates all data defined by the modeller into special internal data structures representing the coefficients of the TIMES matrix applied to each variable of Chapter 5 for each equation of Chapter 6 in which the variable may appear. This step is called Matrix Generation. Once the model is solved (optimised) a Report Writer assembles the results of the run for analysis by the modeller. The matrix generation, report writer, and control files are written in GAMS\(^1\) (the General Algebraic Modelling System), a powerful high-level language specifically designed to facilitate the process of building large-scale optimisation models. GAMS accomplishes this by relying heavily on the concepts of sets, compound indexed parameters, dynamic looping and conditional controls, variables and equations. Thus there is very a strong synergy between the philosophy of GAMS and the overall concept of the RES specification embodied in TIMES, making GAMS very well suited to the TIMES paradigm.

Furthermore, by nature of its underlying design philosophy, the GAMS code is very similar to the mathematical description of the equations provided in Chapter 6. Thus, the approach taken to implement a TIMES model is to “massage” the input data by means of a (rather complex) preprocessor that handles the necessary exceptions that need to be taken into consideration to properly construct the matrix coefficients in a form ready to be applied to the appropriate variables in the respective equations. GAMS also integrates seamlessly with a wide range of commercially available optimisers that are charged with the task of solving the actual TIMES linear (LP) or mixed integer (MIP) problems that represent the desired model. This step is called the Solve or Optimisation step. CPLEX or XPRESS are the optimisers most often employed to solve the TIMES LP and MIP formulations.

The standard TIMES formulation has optional features, such as lumpy investments and endogenous technology learning. The organization and layout of the TIMES code, along with how it is processed by GAMS during a model run, is discussed in detail in PART III. In addition, a modeller experienced in GAMS programming and the details of the TIMES implementation could define additional equation modules or report routine modules based on this organization, which allows the linkage of these modules to the standard TIMES code in a flexible way. However, any thoughts of modifying the core TIMES code should be discussed and coordinated with ETSAP.

To build, run, and analyse a TIMES model, several software tools have been developed in the past or are currently under development, so that the modeller does not need to provide the input information needed to build a TIMES model directly in GAMS. These tools are the model interfaces VEDA-FE and ANSWER-TIMES, as well as the reporting and analysing tool VEDA-BE.

2 Sets

Sets are used in TIMES to group elements or combinations of elements with the purpose of specifying qualitative characteristics of the energy system. One can distinguish between one-dimensional and multi-dimensional sets. The former sets contain single elements, e.g. the set \texttt{prc} contains all processes of the model, while the elements of multi-dimensional sets are a combination of one-dimensional sets. An example for a multi-dimensional set is the set \texttt{top}, which specifies for a process the commodities entering and leaving that process.

Two types of sets are employed in the TIMES framework: user input sets and internal sets. User input sets are created by the user, and used to describe qualitative information and characteristics of the depicted energy system. One can distinguish the following functions associated with user input sets:

- definition of the elements or building blocks of the energy system model (i.e. regions, processes, commodities),
- definition of the time horizon and the sub-annual time resolution,
- definition of special characteristics of the elements of the energy system.

In addition to these user sets, TIMES also generates its own internal sets. Internal sets serve to both ensure proper exception handling (e.g., from what date is a technology available, or in which time-slices is a technology permitted to operate), as well as sometimes just to improve the performance or smooth the complexity of the actual model code.

In the following sections, the user input sets and the internal sets will be presented. A special type of set is a one-dimensional set, also called index, which is needed to build multi-dimensional sets or parameters. At the highest level of the one-dimensional sets are the master or “domain” sets that define the comprehensive list of elements (e.g., the main building blocks of the reference energy system such as the processes and commodities in all regions) permitted at all other levels, with which GAMS performs complete domain checking, helping to automatically ensure the correctness of set definition (for instance, if the process name used in a parameter is not spelled correctly, GAMS will issue a warning). Therefore, before elaborating on the various sets, the indexes used in TIMES are discussed.

2.1 Indexes (One-dimensional sets)

Indexes (also called one-dimensional sets) contain in most cases the different elements of the energy model. A list of all indexes used in TIMES is given in Table 2. Examples of indexes are the set \texttt{prc} containing all processes, the set \texttt{c} containing all commodities, or the set \texttt{all_reg} containing all regions of the model. Some of the one-dimensional sets are subsets of another one-dimensional set, e.g., the set \texttt{r} comprising the so-called internal model regions is a subset of the set \texttt{all_reg}, which in addition also contains the so-called external model regions\textsuperscript{2}. To express that the set \texttt{r} depends on the set \texttt{all_reg}, the master set \texttt{all_reg} is put in brackets after the set name \texttt{r}: \texttt{r(all_reg)}.

The set \texttt{cg} comprises all commodity groups\textsuperscript{3}. Each commodity \texttt{c} is considered as a commodity group with only one element: the commodity itself. Thus the commodity set \texttt{c} is a subset of the commodity group set \texttt{cg}.

Apart from indexes that are under user control, some indexes have fixed elements to serve as indicators within sets and parameters, most of which should not be modified by the user (Table 1). Exceptions to this rule are the sets defined in the file MAPLISTS.DEF. For

\textsuperscript{2} The meaning and the role of internal and external regions is discussed in Section 2.2.

\textsuperscript{3} See Section 2.2.1 for a more in-depth treatment of commodity groups.
while the process groups (prc_grp) listed in Table 1 are used within the code and must not be deleted, other process groups may be added by the user.

### Table 1: Sets with fixed elements

2.2 User input sets

The user input sets contain the fundamental information regarding the structure and the characteristics of the underlying energy system model. The user input sets can be grouped according to the type of information related to them:

- One dimensional sets defining the components of the energy system: regions, commodities, processes;
- Sets defining the Reference Energy System (RES) within each region;
- Sets defining the inter-connections (trade) between regions;
- Sets defining the time structure of the model: periods, timeslices, timeslice hierarchy;
- Sets defining various properties of processes or commodities.

The formulation of user constraints also uses sets to specify the type and the features of a constraint. The structure and the input information required to construct a user constraint is covered in detail in Chapter 6, and therefore will not be presented here.

Most of the set specifications are handled for the user by the user shell through process and commodity characterization, and the user does not need to input these sets directly.

In the following subsections first the sets related to the definition of the RES will be described (subsection 2.2.1), then the sets related to the time horizon and the sub-annual representation of the energy system will be presented (subsection 2.2.2). The mechanism for defining trade between regions of a multi-regional model is discussed in subsection 2.2.3. Finally, an overview of all possible user input sets is given in subsection 2.2.4.

2.2.1 Definition of the Reference Energy System (RES)

A TIMES model is structured by regions (all_r). One can distinguish between external regions and internal regions. The internal regions (r) correspond to regions within the area of study, and for which a RES has been defined by the user. Each internal region may contain processes and commodities to depict an energy system, whereas external regions serve only as origins of commodities (e.g. for import of primary energy resources or for the import of energy carriers) or as destination for the export of commodities. A region is defined as an internal region by putting it in the internal region set (r), which is a subset of the set of all regions all_r. An external region needs no explicit definition, all regions that are member of the set all_r but not member of r are external regions. A TIMES model must consist of at least one internal region, the number of external regions is arbitrary. The main building blocks of the RES are processes (p) and commodities (c), which are connected by commodity flows to form a network. An example of a RES with one internal region (UTOPIA) and two external regions (IMPEXP, MINRNW) is given in Figure 1.

All components of the energy system, as well as nearly the entire input information, are identified by a region index. It is therefore possible to use the same process name in different regions with different numerical data (and description if desired), or even completely different commodities associated with the process.
2.2.1.1 Processes

A process may represent an individual plant, e.g. a specific existing nuclear power plant, or a generic technology, e.g. the coal-fired IGCC technology. TIMES distinguishes three main types of processes:

- Standard processes;
- Inter-regional exchange processes, and
- Storage processes.

2.2.1.1.1 Standard processes

The so-called standard processes can be used to model the majority of the energy technologies, e.g., condensing power plants, heat plants, CHP plants, demand devices such as boilers, coal extraction processes, etc. Standard processes can be classified into the following groups:

- PRE for generic energy processes;
- PRW for material processing technologies (by weight);
- PRV for material processing technologies (by volume);
- REF for refinery processes;
- ELE for electricity generation technologies;
- HPL for heat generation technologies;
- CHP for combined heat and power plants;
- DMD for demand devices;
- DISTR for distribution systems;
- MISC for miscellaneous processes.

The process classification is done via the set \texttt{prc\_map(r, prc\_grp, p)}. This grouping is mainly intended for reporting purposes, but in some cases it also affects the properties of the
processes and the constraint matrix. The set is maintained in the MAPLIST.DEF file, and may be adjusted by user with additional technology groups of interest, with some restrictions as noted in Table 1.

The topology of a standard process is specified by the set \textbf{top}(r,p,c,io) of all quadruples such that the process \textit{p} in region \textit{r} is consuming (\textit{io} = 'IN') or producing (\textit{io} = 'OUT') commodity \textit{c}. Usually, for each entry of the topology set \textit{top} a flow variable (see \textit{VAR_FLO} in Chapter 5) will be created. When the so-called \textit{reduction algorithm} is activated, some flow variables may be eliminated and replaced by other variables (see PART III, Section 3.7 for details).

The activity variable (\textit{VAR_ACT}) of a standard process is in most cases equal to the sum of one or several commodity flows on either the input or the output side of a process. The activity of a process is limited by the available capacity, so that the activity variable establishes a link between the installed capacity of a process and the maximum possible commodity flows entering or leaving the process during a year or a subdivision of a year. The commodity flows that define the process activity are specified by the set \textbf{prc_actunt}(r,p,cg,u) where the commodity index \textit{cg} may be a single commodity or a user-defined commodity group, and \textit{u} is the activity unit. The commodity group defining the activity of a process is also called \textbf{Primary Commodity Group (PCG)}.

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{example.png}
\caption{Example of the definition of a commodity group and the activity of a normal process.}
\end{figure}

User-defined commodity groups are specified by means of the set \textbf{com_gmap}(r,cg,c), which indicates the commodities (\textit{c}) belonging to the group (\textit{cg}). Once a user-defined commodity group has been defined, one can use it for any processes for defining attributes that require a commodity group (not only for the definition of the process activity, but also for other purposes, e.g., in the transformation equation EQ_PTRANS), as long as the members of the group are valid for the particular process and the process characteristic to be defined.

An example for the definition of the activity of a process is shown in Figure 2. In order to define the activity of the process SRE as the sum of the two output flows of gasoline (GSL) and diesel (DSL), one has to define a commodity group called CG_SRE containing these two commodities. The name of the commodity group can be arbitrarily chosen by the modeller.

10 Important cases are the process type CHP, which activates the CHP attributes, storage process indicators (STG,STS,STK,NST), and material conversion process types PRW and PRV, which may affect the creation of the internal set \textbf{prc_spg} (see Table 5).
In addition to the activity of a process, one has to define the capacity unit of the process. This is done by means of the set \( \text{prc\_capunt}(r,p,\text{cg},u) \), where the index \( \text{cg} \) denotes the primary commodity group. In the example in Figure 3 the capacity of the refinery process is defined in mtoe/a (megatonne oil equivalent). Since the capacity and activity units are different (mtoe for the capacity and PJ for the activity), the user has to supply the conversion factor from the energy unit embedded in the capacity unit to the activity unit. This is done by specifying the parameter \( \text{prc\_capact}(r,p) \). In the example \( \text{prc\_capact} \) has the value 41.868.

![Diagram](image)

**Figure 3: Example of the definition of the capacity unit**

It might occur that the unit in which the commodity(ies) of the primary commodity group are measured, is different from the activity unit. An example is shown in Figure 4. The activity of the transport technology CAR is defined by commodity TX1, which is measured in passenger kilometres PKM. The activity of the process is, however, defined in vehicle kilometres VKM, while the capacity of the process CAR is defined as number of cars NOC.

![Diagram](image)

**Figure 4: Example of different activity and commodity units**
The conversion factor from capacity to activity unit \texttt{prc\_capact} describes the average mileage of a car per year. The process parameter \texttt{prc\_actflo(r,y,p cg)} contains the conversion factor from the activity unit to the commodity unit of the primary commodity group. In the example this factor corresponds to the average number of persons per car (1.5).

2.2.1.1.2 Inter-regional exchange processes

Inter-regional exchange (IRE) processes are used for trading commodities between regions. They are needed for linking internal regions with external regions as well as for modelling trade between internal regions. A process is specified as an inter-regional exchange process by specifying it as a member of the set \texttt{prc\_map(r,IRE,p)}. If the exchange process is connecting internal regions, this set entry is required for each of the internal regions trading with region \texttt{r}. The topology of an inter-regional exchange process \texttt{p} is defined by the set \texttt{top\_ire(all_reg,com,all_r,c,p)} stating that the commodity \texttt{com} in region \texttt{all_reg} is exported to the region \texttt{all_r} (the traded commodity may have a different name \texttt{c} in region \texttt{all_r} than in region \texttt{all_reg}). For example the topology of the export of the commodity electricity (ELC\_F) from France (FRA) to Germany (GER), where the commodity is called ELC\_G via the exchange process (HV\_GRID) is modelled by the \texttt{top\_ire} entry:

\texttt{top\_ire('FRA', 'ELC\_F', 'GER', 'ELC\_G', 'HV\_GRID')}

The first pair of region and commodity ('FRA', 'ELC\_F') denotes the origin and the name of the traded commodity, while the second pair ('GER', 'ELC\_G') denotes the destination. The name of the traded commodity can be different in both regions, here 'ELC\_F' in France and 'ELC\_G' in Germany, depending on the chosen commodity names in both regions. As with standard processes, the activity definition set \texttt{prc\_actunt(r,p cg,u)} has to be specified for an exchange process belonging to each internal region. The special features related to inter-regional exchange processes are described in subsection 2.2.3.

2.2.1.1.3 Storage processes

Storage processes are used to store a commodity either between periods or between timeslices. A process \texttt{(p)} can be specified to be an inter-period storage (IPS) process for commodity \texttt{(c)} by defining the process to be of the type 'STK' and \texttt{c} as its PCG (or, alternatively, including it as a member of the set \texttt{prc\_stgips(r,p,c)}). In a similar way, a process is characterised as a timeslice storage by defining the process to be of the type 'STG' and \texttt{c} as its PCG (alternatively, by inclusion in the set \texttt{prc\_stgtss(r,p,c)}). A special case of timeslice storage is a so-called night-storage device (NST) where the commodity for charging and the one for discharging the storage are different. An example for a night storage device is an electric heating technology which is charged during the night using electricity and produces heat during the day. Including a process in the set \texttt{prc\_nstts(r,p,s)} indicates that it is a night storage device which is charged in timeslice(s) \texttt{s}. More than one timeslice can be specified as charging timeslices, the non-specified timeslices are assumed to be discharging timeslices. The charging and discharging commodity of a night storage device are specified by the topology set \texttt{(top)}. It should be noted that for inter-period storage and normal timeslice storage processes (non-NST) the commodity entering and leaving the storage (the charged and discharged commodity) should be a member of the PCG (and both should be, if they are different). Other auxiliary commodity flows are also permitted in combination with these two storage types, by including them in the topology (see Section 4.3.5).

As for standard processes, the flows that define the activity of a storage process are identified by providing the set \texttt{prc\_actunt(r,p,c)} entry. In contrast to standard processes, the activity of a storage process is however interpreted as the amount of the commodity being
stored in the storage process. Accordingly the capacity of a storage process describes the maximum commodity amount that can be kept in storage.

Internally, a prc_map(r,'STG',p) entry is always generated for all storage processes to put the process in the group of storage processes. A further prc_map entry is created to specify the type of storage ('STK' for inter-period storage, 'STS' for general time-slice storage and 'NST' for a night-storage device), unless already defined so by the user.

2.2.1.2 Commodities

As mentioned before, the set of commodities (c) is a subset of the commodity group set (cg). A commodity in TIMES is characterised by its type, which may be an energy carrier ('NRG'), a material ('MAT'), an emission or environmental impact ('ENV'), a demand commodity ('DEM') or a financial resource ('FIN'). The commodity type is indicated by membership in the commodity type mapping set (com_tmap(r,com_type,c)). The commodity type affects the default sense of the commodity balance equation. For NRG, ENV and DEM the commodity production is normally greater than or equal to consumption, while for MAT and FIN the default commodity balance constraint is generated as an equality. The type of the commodity balance can be modified by the user for individual commodities by means of the commodity limit set (com_lim(r,c,lim)). The unit in which a commodity is measured is indicated by the commodity unit set (com_unit(r,c,units_com)). The user should note that within the GAMS code of TIMES no unit conversion, e.g., of import prices, takes place when the commodity unit is changed from one unit to another one. Therefore, the proper handling of the units is entirely the responsibility of the user (or the user interface).

2.2.2 Definition of the time structure

2.2.2.1 Time horizon

The time horizon for which the energy system is analysed may range from one year to many decades. The time horizon is usually split into several periods which are represented by so-called milestone years (t(allyear) or milestoneyr(allyear), see Figure 5). Each milestone year represents a point in time where decisions may be taken by the model, e.g. installation of new capacity or changes in the energy flows. The activity and flow variables used in TIMES may therefore be considered as average values over a period. The shortest possible duration of a period is one year. However, in order to keep the number of variables and equations at a manageable size, periods are usually comprised of several years. The durations of the periods do not have to be equal, so that it is possible that the first period, which usually represents the past and is used to calibrate the model to historic data, has a length of one year, while the following periods may have longer durations. Thus in TIMES both the number of periods and the duration of each period are fully under user control. The beginning year of a period t, B(t), and its ending year, E(t), have to be specified as input parameters by the user (see Table 13 in subsection 3.1.3).

To describe capacity installations that took place before the beginning of the model horizon, and still exist during the modeling horizon, TIMES uses additional years, the so-called past years (pastyear(allyear)), which identify the construction completion year of the already existing technologies. The amount of capacity that has been installed in a pastyear is specified by the parameter NCAP_PASTI(r,allyear,p), also called past investment. For a process, an arbitrary number of past investments may be specified to reflect the age structure in the existing capacity stock. The union of the sets milestoneyr and pastyear is called modelyear (or v). The years for which input data is provided by the user are called datayears (datayear(allyear)). The datayears do not have to coincide with modelyears, since the preprocessor will interpolate or extrapolate the data internally to the modelyears. All pastyears
are by default included in datayears, but, as a general rule, any other years for which input data is provided should be explicitly included in the set datayear or that information will not be seen by the model. Apart from a few exceptions (see Table 3), all parameter values defined for years other than datayears (or pastyears) are ignored by the model generator. Due to the distinction between of modelyears and datayears, the definition of the model horizon, e.g., the duration and number of the periods, may be changed without having to adjust the input data to the new periods. The rules and options of the inter- and extrapolation routine are described in more detail in subsection 3.1.1.

One should note that it is possible to define past investments (NCAP_PASTI) not only for pastyears but also for any years within the model horizon, including the milestone years. Since the first period(s) of a model may cover historical data, it is useful to store the already known capacity installations made during this time-span as past investments and not as a bound on new investments in the model database. If one later changes the beginning of the model horizon to a more recent year, the capacity data of the first period(s) do not have to be changed, since they are already stored as past investments. This feature therefore supports the decoupling of the datayears, for which input information is provided, and the definition of the model horizon for which the model is run, making it relatively easy to change the definition of the modeling horizon. Defining past investments for years within the actual model horizon may also be useful for identifying already planned (although not yet constructed) capacity expansions in the near future.\(^{11}\)

---

\(^{11}\) In this case the model may still decide to add additional new capacity, if this is economical and not inhibited by any investment bounds.

2.2.2.2 Timeslices

The milestone years can be further divided in sub-annual timeslices in order to describe for the changing electricity load within a year, which may affect the required electricity generation capacity, or other commodity flows that need to be tracked at a finer than annual resolution. Timeslices may be organised into four hierarchy levels only: 'ANNUAL', 'SEASON', 'WEEKLY' and 'DYNITE' defined by the internal set `tslvl`. The level ANNUAL consists of only one member, the predefined timeslice 'ANNUAL', while the other levels may include an arbitrary number of divisions. The desired timeslice levels are activated by the user providing entries in set `ts_group(r,tslvl,s)`, where also the individual user-provided timeslices (s) are assigned to each level. An additional user input set `ts_map(r,s1,s2)` is needed to determine the structure of a timeslice tree, where timeslice s1 is defined as the parent node of s2. Figure 6 illustrates a timeslice tree, in which a year is divided into four seasons consisting of working days and weekends, and each day is further divided into day and night timeslices. The name of each timeslice has to be unique in order to be used later as an index in other sets and parameters. Not all timeslice levels have to be utilized when building a timeslice tree, for example one can skip the 'WEEKLY' level and directly connect the seasonal timeslices with the daynite timeslices. The duration of each timeslice is expressed as a fraction of the year by

---

The purpose of this table is to list those parameters whose year values are independent of the input `datayears` associated with most of the regular parameters, and therefore need not be included in the set `datayear`. For example, a value for `MULTI(j,'2012')` would not require including 2012 in `datayears` if 2012 were not relevant to the other input parameters.
the parameter G\_YRFR(r,s). The user is responsible for ensuring that each lower level group sums up properly to its parent timeslice, as this is not verified by the pre-processor. The definition of a timeslice tree is region-specific. When different timeslice names and durations are used in two regions connected by exchange processes, the mapping parameters \textsc{ire\_cct}(r,c,reg,com) for commodities and \textsc{ire\_tscvt}(r,s,reg,ts) for timeslices have to be provided by the user to map the different timeslice definitions. When the same timeslice definitions are used, these mapping tables do not need to be specified by the user.

Commodities may be tracked and process operation controlled at a particular timeslice level by using the sets \textsc{com\_ts}(r,c,ts lvl) and \textsc{prc\_ts}(r,p,ts lvl) respectively. Providing a commodity timeslice level determines for which timeslices the commodity balance will be generated, where the default is 'ANNUAL'. For processes, the set \textsc{prc\_ts} determines the timeslice level of the activity variable. Thus, for instance, condensing power plants may be forced to operate on a seasonal level, so that the activity during a season is uniform, while hydropower production may vary between days and nights, if the 'DAYNITE' level is specified for hydro power plants. Instead of specifying a timeslice level, the user can also identify individual timeslices for which a commodity or a process is available by the sets \textsc{com\_ts}(r,c,s) and \textsc{prc\_ts}(r,p,s) respectively. Note that when specifying individual timeslices for a specific commodity or process by means of \textsc{com\_ts} or \textsc{prc\_ts} they all have to be on the same timeslice level.

The timeslice level of the commodity flows entering and leaving a process are determined internally by the preprocessor. The timeslice level of a flow variable equals the timeslice level of the process when the flow variable is part of the primary commodity group (PCG) defining the activity of the process. Otherwise the timeslice level of a flow variable is set to whichever level is finer, that of the commodity or the process.

---

13 By setting G\_YRFR(r,s)=0 one can exclude any individual timeslices from specific regions, even if only a global timeslice tree is defined for all regions (as it is the case when using VEDA-FE). In this way each region can employ a different subset of the global tree.
### 2.2.3 Multi-regional models

If a TIMES model consists of several internal regions, it is called a multi-regional model. Each of the internal regions contains a unique RES to represent the particularities of the region. As already mentioned, the regions can be connected by inter-regional exchange processes to enable trade of commodities between the regions. Two types of trade activities can be depicted in TIMES: bi-lateral trade between two regions and multilateral trade between several supply and demand regions.

Bi-lateral trade takes place between specific pairs of regions. A pair of regions together with an exchange process and the direction of the commodity flow are first identified, where the model ensures that trade through the exchange process is balanced between these two regions (whatever amount is exported from region A to region B must be imported by region B from region A, possibly adjusted for transportation losses). The basic structure is shown in Figure 7. Bi-lateral trading may be fully described in TIMES by defining an inter-regional exchange process and by specifying the two pair-wise connections by indicating the regions and commodities be traded via the set \( \text{top}_i\text{re}(r,c,\text{reg},\text{com},p) \). If trade should occur only in one direction then only that direction is provided in the set \( \text{top}_i\text{re} \) (export from region r into region reg). The process capacity and the process related costs (e.g. activity costs, investment costs) of the exchange process can be described individually for both regions by specifying the corresponding parameters in each regions. If for example the investment costs for an electricity line between two regions A and B are 1000 monetary units (MU) per MW and 60% of these investment costs should be allocated to region A and the remaining 40% to region B, the investment costs for the exchange process have to be set to 600 MU/MW in region A and to 400 MU/MW in region B.

Bi-lateral trade is the most detailed way to specify trade between regions. However, there are cases when it is not important to fully specify the pair of trading regions. In such cases, the so-called multi-lateral trade option decreases the size of the model while preserving enough flexibility. Multi-lateral trade is based on the idea that a common marketplace exists for a traded commodity with several supplying and several consuming regions for the commodity, e.g. for crude oil or GHG emission permits. To facilitate the modelling of this kind of trade scheme the concept of marketplace has been introduced in TIMES. To model a marketplace first the user has to identify one internal region that participates both in the production and consumption of the traded commodity. Then only one exchange process is

![Figure 7: Bilateral trade in TIMES](image)
used to link the supply and demand regions with the marketplace region using the set `top_ire`.\textsuperscript{14}

The following example illustrates the modelling of a marketplace in TIMES. Assume that we want to set up a market-based trading where the commodity CRUD can be exported by regions A, B, C, and D, and that it can be imported by regions C, D, E and F (Figure 8).

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure8.png}
\caption{Example of multi-lateral trade in TIMES}
\end{figure}

First, the exchange process and marketplace should be defined. For example, we could choose the region C as the marketplace region. The exchange process has the name XP. The trade possibilities can then be defined simply by the following six `top_ire` entries:

\begin{verbatim}
SET PRC / XP /;
SET TOP_IRE /  
   A .CRUD .C .CRUD .XP  
   B .CRUD .C .CRUD .XP  
   D .CRUD .C .CRUD .XP  
   C .CRUD .D .CRUD .XP  
   C .CRUD .E .CRUD .XP  
   C .CRUD .F .CRUD .XP  
/;
\end{verbatim}

To complete the RES definition of the exchange process, only the set `prc_actunt(r,p,c,u)` is needed to define the units for the exchange process XP in all regions:

\begin{verbatim}
SET PRC.ACTUNT /  
   A .XP .CRUD .PJ  
   B .XP .CRUD .PJ  
   C .XP .CRUD .PJ  
   D .XP .CRUD .PJ  
   E .XP .CRUD .PJ  
   F .XP .CRUD .PJ  
/;
\end{verbatim}

\textsuperscript{14} Note however that some flexibility is lost when using multilateral trade. For instance, it is not possible to express transportation costs in a fully accurate manner, if such cost depends upon the precise pair of trading regions in a specific way.
These definitions are sufficient for setting up of the market-based trade. Additionally, the user can of course specify various other data for the exchange processes, for example investment and distribution costs, and efficiencies.

### 2.2.4 Overview of all user input sets

All the input sets which are under user control in TIMES are listed in Table 4. For a few sets default settings exist that are applied if no user input information is given. Set names starting with the prefix ‘com_’ are associated with commodities, the prefix ‘prc_’ denotes process information and the prefix ‘uc_’ is reserved for sets related to user constraints. Column 3 of Table 4 is a description of each set. In some cases (especially for complex sets), two (equivalent) descriptions may be given, the first in general terms, followed by a more precise description within square brackets, given in terms of n-tuples of indices.

**Remark**

Sets are used in basically two ways:
- as the domain over which summations must be effected in some mathematical expression, or
- as the domain over which a particular expression or constraint must be enumerated (replicated).

In the case of n-dimensional sets, some indexes may be used for enumeration and others for summation. In each such situation, the distinction between the two uses of the indexes is made clear by the way each index is used in the expression.

An example will illustrate this important point: consider the 4-dimensional set \( \text{top} \), having indexes \( r, p, c, io \) (see table 4 for its precise description). If some quantity \( A(r,p,c,io) \) must be enumerated for all values of the third index (\( c=\text{commodity} \)) and of the last index (\( io=\text{orientation} \)), but summed over all processes (\( p \)) and regions (\( r \)), this will be mathematically denoted:

\[
\text{EXPRESSION}_1_{c,io} = \sum_{r, p, c, \text{ io}=\text{top}} A(r, p, c, io)
\]

It is thus understood from the indexes listed in the name of the expression (\( c, io \)), that these two indexes are being enumerated, and thus, by deduction, only \( r \) and \( p \) are being summed upon. Thus the expression calculates the total of \( A \) for each commodity \( c \), in each direction \( io \) (‘IN’ and ‘OUT’), summed over all processes and regions.

Another example illustrates the case of nested summations, where index \( r \) is enumerated in the inner summation, but is summed upon in the outer summation. Again here, the expression is made unambiguous by observing the positions of the different indexes (for instance, the outer summation is done on the \( r \) index)

\[
\text{EXPRESSION}_2_{c,io} = \sum_{r, p, c, \text{io}=\text{top}} B(r) \sum_{p} A(r, p)
\]
Table 4: User input sets in TIMES

<td>Set of pairs ({\text{all}_r,\text{uc}_n}) indicating that the user constraint (\text{uc}_n) is summing over all specified regions (\text{all}_r) (that is these constraints do not have a region index). Note that depending on the specified regions in (\text{ur}_r_\text{sum}), the summation may be done only over a subset of all model regions. For example if the model contains the regions FRA, GER, ESP and one wants to create a user constraint called GHG summing over the regions FRA and GER but not ESP, the set (\text{uc}_r_\text{sum}) contains has the two entries {‘FRA’, ‘GHG’} and {‘GER’, ‘GHG’}.</td>
</tr>
<tr>
<td>uc_t_each (r,uc_n,t)</td>
<td></td>
<td>Indicator that the user constraint (\text{uc}_n) is to be generated for each specified period (t).</td>
</tr>
<tr>
<td>uc_t_succ (r,uc_n,t)</td>
<td></td>
<td>Indicator that the user constraint (\text{uc}_n) is to be generated between the two successive periods (t) and (t+1).</td>
</tr>
<tr>
<td>uc_t_sum (r,uc_n,t)</td>
<td></td>
<td>Indicator that the user constraint (\text{uc}_n) is to be generated summing over the periods (t).</td>
</tr>
<tr>
<td>uc_ts_each (r,uc_n,s)</td>
<td></td>
<td>Indicator that the user constraint (\text{uc}_n) will be generated for each specified timeslice (s).</td>
</tr>
<tr>
<td>uc_ts_sum (r,uc_n,s)</td>
<td></td>
<td>Indicator that the user constraint (\text{uc}_n) is to be generated summing over the specified timeslice (s).</td>
</tr>
<tr>
<td>uc_tsl (r,uc_n,side,tslvl)</td>
<td></td>
<td>Indicator of the target timeslice level (\text{tslvl}) of a timeslice-dynamic (or pseudo-dynamic) user constraint (\text{uc}_n).</td>
</tr>
<tr>
<td>v</td>
<td>modlyear</td>
<td>Union of the sets (\text{pastyear}) and (t) corresponding to all the years (periods) of a model run (thus actually an internal set).</td>
</tr>
</tbody>
</table>
2.3 Definition of internal sets

The sets internally derived by the TIMES model generator are given in Table 5. The list of internal sets presented here concentrates on the ones frequently used in the model generator and the ones used in the description of the model equations in Chapter 6. Some internal sets are omitted from Table 5 as they are strictly auxiliary sets of the preprocessor whose main purpose is the reduction of the computation time for preprocessor operations.

Table 5: Internal sets in TIMES

<table>
<thead>
<tr>
<th>Set ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>afs</td>
<td>Indicator that the internal parameter COEF_AF, which is used as coefficient of the capacity (new investment variable VAR_NCAP plus past investments NCAP_PASTI) in the capacity utilization constraint EQ(1),_CAPACT, exists.</td>
</tr>
<tr>
<td>bohyear</td>
<td>Set allyear plus element 'BOH' (Beginning Of Horizon).</td>
</tr>
<tr>
<td>dm_year</td>
<td>Union of sets datayear and modlyear</td>
</tr>
<tr>
<td>eachyear</td>
<td>Set of all years between scalars MINYR (first year needed for cost calculation in objective function) and MIYR_VL + DUR_MAX (estimation of last year possible cost terms may occur).</td>
</tr>
<tr>
<td>eohyear</td>
<td>Set allyear plus element 'EOH' (Ending Of Horizon)</td>
</tr>
<tr>
<td>eohyears</td>
<td>Set of all years between scalars MINYR (first year needed for cost calculation in objective function) and MIYR_VL (last year of model horizon).</td>
</tr>
<tr>
<td>finest</td>
<td>Set of finest timeslices s used in region r.</td>
</tr>
<tr>
<td>fs_emis</td>
<td>Indicator that the flow variable (VAR_FLO) associated with emission com can be replaced by the flow variable of c multiplied by the emission factor FLO_SUM, which is used in the transformation equation (EQ_PTRANS) between the commodity group cg and the commodity com; used in the reduction algorithm (see Part III).</td>
</tr>
<tr>
<td>g_rcur</td>
<td>Indicator of main currency cur by region r. For regions having several discounted currencies, the one having highest present value factors is selected; used for undiscounting the solution marginals.</td>
</tr>
<tr>
<td>invspred</td>
<td>Set of investment years y and commissioning years k belonging to the investment spread starting with year and having jot number of steps (used for investment and fixed cost accounting).</td>
</tr>
<tr>
<td>invstep</td>
<td>Set of investment years y belonging to the investment spread starting with year and having jot number of steps (used for investment and fixed cost accounting).</td>
</tr>
<tr>
<td>miyr_1</td>
<td>First milestoneyr.</td>
</tr>
<tr>
<td>no_act</td>
<td>List of processes p in region r not requiring the activity variable; used in reduction algorithm</td>
</tr>
<tr>
<td>no_cap</td>
<td>List of processes p in region r not having any capacity related input parameters; used in reduction algorithm.</td>
</tr>
<tr>
<td>no_rvp</td>
<td>New investment in process p in region r is not possible in period v and previously installed capacity does not exist anymore.</td>
</tr>
</tbody>
</table>

18 Name of the internal set as used in this documentation and the GAMS code.
19 Index domain of the internal set is given in brackets (Note: the symbols y, y1, y2, k, and ll all refer to year).
20 The asterisk denotes in the modeling system GAMS a wildcard, so that domain checking is disabled and any index may be used.
<table>
<thead>
<tr>
<th>Set ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>obj_1a</td>
<td>Investment case small investment (NCAPILED/D(v) ≤ GILEDNO) and no repetition of investment (NCAPTILIFE + NCAPILED ≥ D(v)) for process p in region r and vintage period v.</td>
</tr>
<tr>
<td>obj_1b</td>
<td>Investment case small investment (NCAPILED/D(v) ≤ GILEDNO) and repetition of investment (NCAPTILIFE + NCAPILED &lt; D(v)) for process p in region r and vintage period v.</td>
</tr>
<tr>
<td>obj_2a</td>
<td>Investment case large investment (NCAPILED/D(v) &gt; GILEDNO) and no repetition of investment (NCAPTILIFE + NCAPILED ≥ D(v)) for process p in region r and vintage period v.</td>
</tr>
<tr>
<td>obj_2b</td>
<td>Investment case large investment (NCAPILED/D(v) &gt; GILEDNO) and repetition of investment (NCAPTILIFE + NCAPILED &lt; D(v)) for process p in region r and vintage period v.</td>
</tr>
<tr>
<td>obj_idc</td>
<td>Summation control for calculating the interest during constriction (IDC) for investment Cases 2.a and 2.b.</td>
</tr>
<tr>
<td>obj_sumii</td>
<td>Summation control for investment and capacity related taxes and subsidies of the in the annual objective function, with lifetime life, spread starting in commissioning year y, having jot number of steps in the spread, and vintage period v.</td>
</tr>
<tr>
<td>obj_sumiii</td>
<td>Summation control for decommissioning costs with for the running year index y of annual objective function, vintage period v, startup-year ll, and commissioning year k (e.g. for spreading decommissioning costs over decommissioning time).</td>
</tr>
<tr>
<td>obj_sumiv</td>
<td>Summation control for fixed costs in the annual objective function with lifetime life, spread starting in commissioning year y, having jot number of steps in the spread, and vintage period v.</td>
</tr>
<tr>
<td>obj_sumivs</td>
<td>Summation control for decommissioning surveillance costs with running year index y of annual objective function, vintage period v and commissioning year k.</td>
</tr>
<tr>
<td>obj_sums</td>
<td>Indicator that process p in region r with vintage period v has a salvage value for investments with a (technical) lifetime that extends past the model horizon.</td>
</tr>
<tr>
<td>obj_sums3</td>
<td>Indicator that process p in region r with vintage period v has a salvage value associated with the decommissioning or surveillance costs.</td>
</tr>
<tr>
<td>obj_sumii</td>
<td>Indicator that for commissioning years k process p in region r with vintage period v has a salvage value due to investment, decommissioning or surveillance costs arising from the technical lifetime extending past the model horizon.</td>
</tr>
<tr>
<td>periodyr</td>
<td>Mapping of individual years y to the modyear (milestonyr or pastyear; v) period they belong to; if v is a pastyear, only the pastyear itself belongs to the period; for the last period of the model horizon also the years until the very end of the model accounting horizon (MIYR_VL + DUR_MAX) are elements of periodyr.</td>
</tr>
<tr>
<td>prc_act</td>
<td>Indicator that a process p in region r needs an activity variable (used in reduction algorithm).</td>
</tr>
<tr>
<td>prc_cap</td>
<td>Indicator that a process p in region r needs a capacity variable (used in reduction algorithm).</td>
</tr>
<tr>
<td>prc_spgr</td>
<td>Shadow primary group (SPG) of a process p; all commodities on the opposite process side of the primary commodity group (PCG) which have the same commodity type as the PCG, usually internally determined (though it may be specified by the user under special circumstances (e.g., when not all the commodities on the opposite side of the process, which should be in the SPG, are of the same commodity type com_type).</td>
</tr>
</tbody>
</table>

If no commodity of the same type is found:
if PCG is of type 'DEM' and process is a material processing process (PRV or PRW), then the SPG contains all material commodities on the SPG side; otherwise the SPG is selected as the first type among the commodity types on the SPG side, in the flowing order:
When PCG type is DEM: (NRG, MAT, ENV)
When PCG type is NRG: (NRG, MAT, ENV)
When PCG type is MAT: (NRG, MAT, ENV)
When PCG type is ENV: (NRG, MAT, DEM)
<table>
<thead>
<tr>
<th>Set ID&lt;sup&gt;18&lt;/sup&gt;</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>prc_stgips&lt;sup&gt;19&lt;/sup&gt; (r,p,c)</td>
<td>Set of triplets ( (r,p,c) ) such that process ( p ) is an inter-period storage for the commodity ( c ) in region ( r ); the commodity ( c ) enters and/or leaves the storage according to the set ( \text{top} ); the storage can only operate at the ANNUAL level.</td>
</tr>
<tr>
<td>prc_stgtss (r,p,c)</td>
<td>Set of triplets ( (r,p,c) ) such that process ( p ) is a storage process between timeslices (e.g., seasonal hydro reservoir, day/night pumped storage) for commodity ( c ) in region ( r ); commodity ( c ) enters and/or leaves the storage according to set ( \text{top} ); the storage operates at the timeslice level ( \text{prc_tsl} ).</td>
</tr>
<tr>
<td>rc (r,c)</td>
<td>List of all commodities ( c ) found in region ( r ).</td>
</tr>
<tr>
<td>rc_agg (r,c,lim)</td>
<td>Indicator of which commodities ( c ) are aggregated into other commodities by aggregation type ( \text{lim} ).</td>
</tr>
<tr>
<td>rc_cumcom (r,com_var,y1,y2,c)</td>
<td>Indicator of a cumulative constraint of type ( \text{com_var} ) defined for commodity ( c ) between years ( y1 ) and ( y2 ).</td>
</tr>
<tr>
<td>rcs_combal (r,t,c,s,bd)</td>
<td>Steps ( j ) used in direction ( \text{bd} ) for the elastic demand formulation of commodity ( c ).</td>
</tr>
<tr>
<td>rcs_comprd (r,t,c,s,bd)</td>
<td>Indicator of which timeslices ( (s) ) associate with commodity ( c ) in region ( r ) for time period ( t ) the commodity balance equation ( \text{EQ(l)}_\text{COMBAL} ) is to be generated, with a constraint type corresponding to ( \text{bd} ).</td>
</tr>
<tr>
<td>rcs_comts (r,c,s)</td>
<td>All timeslices ( s ) being at or above timeslice level ( \text{com_tsl} ) of commodity ( c ) in region ( r ).</td>
</tr>
<tr>
<td>rdcur (r,cur)</td>
<td>List of currencies ( \text{cur} ) that are discounted (G_DRATE provided) in each region ( r ).</td>
</tr>
<tr>
<td>rhs_combal (r,t,c,s)</td>
<td>Indicator that the commodity net variable (VAR_COMNET) is required in commodity balance (EQE_COMBAL), owing to bounds/costs imposed on the net amount.</td>
</tr>
<tr>
<td>rhs_comprd (r,t,c,s)</td>
<td>Indicator that the commodity production variable (VAR_COMPRD) is required in commodity balance (EQE_COMPRD), owing to a limit/costs imposed on the production.</td>
</tr>
<tr>
<td>rp (r,p)</td>
<td>List of processes ( (p) ) in each region ( (r) ).</td>

</tr>
<tr>
<td>rp_ups (r,p,tsvl,lim)</td>
<td>Timeslices ( (s) ) of a process ( (p) ) in a region ( (r) ) during which start-ups are permitted (used for processes in the set ( \text{rp_upl}(r,p,\text{FX}) )).</td>
</tr>
<tr>
<td>rpc (r,p,c)</td>
<td>List of commodities ( (c) ) associated with a process ( (p) ) in region ( (r) ) by ( \text{top} ) or ( \text{top_ire} ).</td>
</tr>
<tr>
<td>Set ID</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>rpc_act(r,p,c)</td>
<td>Indicator that the primary commodity group of a process (p), except exchange processes (see rpc_aire) consists of only one commodity (c), enabling the corresponding flow variable to be replaced by the activity variable (used in reduction algorithm).</td>
</tr>
<tr>
<td>rpc_aire(r,p,c)</td>
<td>Indicator that the primary commodity group of an exchange process (p) consists of only one commodity (c), enabling the corresponding flow variable to be replaced by the activity variable (used in reduction algorithm).</td>
</tr>
<tr>
<td>rpc_capflo(r,v,p,c)</td>
<td>Indicator that a commodity flow c in region r is associated with the capacity of a process (p, due to NCAP_ICOM, NCAP_OCOM, or NCAP_COM being provided).</td>
</tr>
<tr>
<td>rpc_cumflo(r,p,c,y1,y2)</td>
<td>Indicator of a cumulative constraint defined for commodity flow c of process p between years y1 and y2.</td>
</tr>
<tr>
<td>rpc_noflo(r,p,c)</td>
<td>A subset of rpc_capflo indicating those processes (p) in a region (r) where a commodity (c) is only consumed or produced through capacity based flows, and thus has no flow variable for the commodity.</td>
</tr>
<tr>
<td>rpc_emis(r,p,cg)</td>
<td>Indicator that the flow variable of an emission commodity (cg) associated with process (p) in a region (r) can be replaced by the fuel flow causing the emission multiplied by the emission factor (used in reduction algorithm).</td>
</tr>
<tr>
<td>rpc_eqire(r,p,c)</td>
<td>Indicator of the commodities (c) associated with inter-regional exchange processes (p) in region (r) for which an inter-region exchange equation (EQ_IRE) is to be generated; the set does not contain the marketplace region (rpc_market).</td>
</tr>
<tr>
<td>rpcc_ffunc(r,p,c)</td>
<td>Flow variable of a commodity (c) associated with a process (p) that can be replaced by another flow variable of the process, due to a direct FLO_FUNC or FLO_SUM relationship.</td>
</tr>
<tr>
<td>rpc_emis(r,p,c)</td>
<td>Commodity (c) imported or exported (ie='IMP'/EXP') by process p in a region (all_r).</td>
</tr>
<tr>
<td>rpc_market(all_r,p,c,ie)</td>
<td>List of market regions (subset of all_r) that trade a commodity (c) through a process (p) either by only multidirectional export links (ie='EXP') or by both import and export links (ie='IMP'). The market structure is user-defined through the set top_ire.</td>
</tr>
<tr>
<td>rpc_pg(r,p,cg,c)</td>
<td>Mapping of the commodities (c) in a region (r) that belong to the primary commodity group (cg) associated with process p.</td>
</tr>
<tr>
<td>rpc_spg(r,p,c)</td>
<td>The list of commodities (c) in a region (r) belonging to the shadow primary group of process (p).</td>
</tr>
<tr>
<td>rpc_stg(r,p,c)</td>
<td>List of stored (charged/discharged) commodities (c) of storage processes (p) in region (r).</td>
</tr>
<tr>
<td>rpc_stgn(r,p,c,io)</td>
<td>List of those stored (charged/discharged) commodities (c) of storage processes (p) in region (r), which are connected to the commodity balance on one side (io) only.</td>
</tr>
<tr>
<td>rpc_g_ptran(r,p,c)</td>
<td>Indicator of the transformation equations (EQ_PTRANS) that can be eliminated by the reduction algorithm.</td>
</tr>
<tr>
<td>rpcs_var(r,p,c,s)</td>
<td>The list of valid timeslices for the flow variable (VAR_FLO) of commodity c associated with process p in region r; flow variables of commodities which are part of the primary commodity group have the timeslice resolution of the process (rpc_tsl), while all other flow variables are created according to the rps_s1 timeslices.</td>
</tr>
<tr>
<td>rps_prcts(r,p,s)</td>
<td>All (permitted) timeslices (s) at or above the process (p) timeslice level (rpc_tsl) in a region (r).</td>
</tr>
<tr>
<td>rps_s1(r,p,s)</td>
<td>All (permitted) timeslices (s) belonging to the finest timeslice level of the process (p, rpc_tsl) and the commodity timeslice level (com_tsl) of the shadow primary commodity group.</td>
</tr>
<tr>
<td>rps_s2(r,p,s)</td>
<td>For an ANNUAL level NST process, contains all permitted timeslices (s) at the level above the finest commodity timeslice levels (com_tsl) of the shadow primary group (spg). For all other processes, rps_s2 = rps_s1.</td>
</tr>
<tr>
<td>rps_stg(r,p,s)</td>
<td>Process level timeslices (s) of timeslice storage process (p) in a region (r).</td>
</tr>
<tr>
<td>rreg(all_reg,all_r)</td>
<td>Indicator that trade exists from region all_reg to region all_r.</td>
</tr>
<tr>
<td>Set ID&lt;sup&gt;18&lt;/sup&gt;</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>rs_below&lt;sup&gt;19&lt;/sup&gt; &lt;br&gt; (all_r,ts,s)</td>
<td>All timeslices (s) strictly below the higher timeslice (ts) in the timeslice tree.</td>
</tr>
<tr>
<td>rs_below1 &lt;br&gt; (all_r,ts,s)</td>
<td>All timeslices (s) immediately (one level) below the higher timeslice (ts) in the timeslice tree.</td>
</tr>
<tr>
<td>rs_tree &lt;br&gt; (all_r,ts,s)</td>
<td>For a timeslice (ts) all timeslices (s) that are on the same paths within the timeslice tree, e.g. if ts=SP_WD in Fig. 6, valid timeslices s are: ANNUAL, SP, SP_WD, SP_WD_D, SP_WD_N.</td>
</tr>
<tr>
<td>rtc_cumnet &lt;br&gt; (r,t,c)</td>
<td>Indicator that the commodity net variable (VAR_COMNET) for commodity c in region r for period t has a cumulative bound applied.</td>
</tr>
<tr>
<td>rtc_cumprd &lt;br&gt; (r,t,c)</td>
<td>Indicator that the commodity production variable (VAR_COMPRD) for commodity c in region r for period t has a cumulative bound applied.</td>
</tr>
<tr>
<td>rttcs_sing &lt;br&gt; (r,t,c,s,io)</td>
<td>Indicator that a commodity (c) is not available in a specific period (t) and timeslice (s), since all the processes producing (io='OUT') or consuming it (io='IN') are turned-off. In the case of io='OUT', the commodity is not available, meaning that processes having only this commodity as input cannot operate. Similar reasoning applies to the case io='IN'.</td>
</tr>
<tr>
<td>rttcs_varc &lt;br&gt; (r,t,c,s)</td>
<td>For commodity (c) in region (r) indicator for the timeslices (s) and the periods (t) the commodity is available.</td>
</tr>
<tr>
<td>rtp = rvp &lt;br&gt; (r,v,p)</td>
<td>Indication of the periods and pastyears for which process (p) in region (r) is available; all other RTP_* control sets are based on this set.</td>
</tr>
<tr>
<td>rtp_capyr &lt;br&gt; (r,v,t,p)</td>
<td>For each vintage period (v) an indication of the periods (t) for which newly installed capacity of process (p) in a region (r) is available, taking into account construction lead-time (NCAPILED) and technical lifetime (NCAP_TLIFE).</td>
</tr>
<tr>
<td>rtp_off &lt;br&gt; (r,t,p)</td>
<td>Indication of the periods (t) in which no new investment is permitted for a process (p) in a region (r).</td>
</tr>
<tr>
<td>rtp_vara &lt;br&gt; (r,t,p)</td>
<td>Indication of the periods (t) for which a process (p) in a region (r) is available.</td>
</tr>
<tr>
<td>rtp_varp &lt;br&gt; (r,t,p)</td>
<td>Indicator that the capacity variable (VAR_CAP) will be generated for process (p) in a region (r) in period (t).</td>
</tr>
<tr>
<td>rtp_vintyr &lt;br&gt; (r,v,t,p)</td>
<td>An indication of for which periods (t) a process (p) in a region (r) is available since it was first installed (v); for vintaged processes (prc_vint) identical to RTP_CPTYR, for non-vintaged processes the v index in the RTP_CPTYR entries is ignored by setting it to t (v = t).</td>
</tr>
<tr>
<td>rpcc &lt;br&gt; (r,t,p,c)</td>
<td>For a process (p) in a region (r) the combination of the periods it is available (rtp) and commodities associated with it (rpcc).</td>
</tr>
<tr>
<td>rtps_off &lt;br&gt; (r,t,p,s)</td>
<td>An indication for process (p) of the timeslices (s) for which the process is turned-off (used in reduction algorithm).</td>
</tr>
<tr>
<td>rtpcs_varf &lt;br&gt; (r,t,p,c,s)</td>
<td>The list of valid timeslices (s) and periods (t) for the flow variable (VAR_FLO) of process (p) and commodity (c); taking into account the availability of the activity, capacity and flow (RTP_VARA, RTPCS_VAR and PRE_OFF). The timeslice level of a flow variable equals the process timeslice level (PRE_TSI) when the flow is part of the primary commodity group of the process. Otherwise the timeslice level of a flow variable is set to the finest level of the commodities in the shadow group (SPG) or the process level, whichever is finer.</td>
</tr>
<tr>
<td>uc_dyndir &lt;br&gt; (r,uc_n,side)</td>
<td>If side = 'RHS', indicator for growth constraints to be generated between the periods t–1 and t; if side = 'LHS', the set is ignored.</td>
</tr>
<tr>
<td>uc_gmap_c &lt;br&gt; (r,uc_n,uc_grptype,c)</td>
<td>Indicator that a commodity variable (VAR_COMCON or VAR_COMPRD) for commodity (c) in a region (r) appears in a user constraint (uc_n).</td>
</tr>
<tr>
<td>uc_gmap_p &lt;br&gt; (r,uc_n,uc_grptype,p)</td>
<td>Indicator that a variable (VAR_ACT, VAR_NCAP or VAR_CAP) associated with a process (p) in a region (r) appears in a user constraint (uc_n).</td>
</tr>
<tr>
<td>uc_gmap_u &lt;br&gt; (r,uc_n,ucn)</td>
<td>Indicator that a variable (VAR_UCRT) associated with a user constraint (ucn) in a region (r) appears in another user constraint (uc_n).</td>
</tr>
<tr>
<td>uc_map_flo &lt;br&gt; (uc_n,r,p,c)</td>
<td>Indicator that the flow variable (VAR_FLO) for region r, process p, and commodity c is involved in a user constraint (uc_n).</td>
</tr>
<tr>
<td>uc_map_ire &lt;br&gt; (uc_n,r,p,c)</td>
<td>Indicator that an import/export (according to TOP_IRE) trade variable (VAR_IRE) for region r, process p, and commodity c is involved in a user constraint (uc_n).</td>
</tr>
<tr>
<td>v</td>
<td>Union of the input sets pastyear and t, corresponding to all the periods of a model run (=modlyear).</td>
</tr>
</tbody>
</table>
3 Parameters

While sets describe structural information of the energy system or qualitative characteristics of its entities (e.g. processes or commodities), parameters contain numerical information. Examples of parameters are the import price of an energy carrier or the investment cost of a technology. Most parameters are time-series where a value is provided (or interpolated) for each year (datayear). The TIMES model generator distinguishes between user input parameters and internal parameters. The former are provided by the modeller (usually by way of a data handling system or “shell” such a VEDA-FE or ANSWER-TIMES), while the latter are internally derived from the user input parameters, in combination with information given by sets, in order to calculate for example the cost coefficients in the objective function. This Chapter first covers the user input parameters in Section 3.1 and then describes the most important internal parameters as far as they are relevant for the basic understanding of the equations (Section 3.2). Section 3.3 presents the parameters used for reporting the results of a model run.

3.1 User input parameters

This section provides an overview of the user input parameters that are available in TIMES to describe the energy system. Before presenting the various parameters in detail in Section 3.1.3 two preprocessing algorithms applied to the user input data are presented, namely the inter-/extrapolation and the inheritance/aggregation routines. User input parameters that are time-dependent can be provided by the user for those years for which statistical information or future projections are available, and the inter-/extrapolation routine described in Section 3.1.1 used to adjust the input data to the years required for the model run. Timeslice dependent parameters do not have to be provided on the timeslice level of a process, commodity or commodity flow. Instead the so-called inheritance/aggregation routine described in Section 3.1.2 assigns the input data from the user provided timeslice level to the appropriate timeslice level as necessary.

3.1.1 Inter- and extrapolation of user input parameters

Time-dependent user input parameters are specified for specific years, the so-called datayears (datayear). These datayears do not have to coincide with the modelyears (v or modelyear) needed for the current run. Reasons for differences between these two sets are for example that the period definition for the model has been altered after having provided the initial set of input data leading to different milestoneyears (t or milestoneyr) or that data are only available for certain years that do not match the modelyears. In order to avoid burdening the user with the cumbersome adjustment of the input data to the modelyears, an inter-/extrapolation (I/E) routine is embedded in the TIMES model generator. The inter-/extrapolation routine distinguishes between a default inter-/extrapolation that is automatically applied to the input data and an enhanced user-controlled inter-/extrapolation that allows the user to specify an inter-/extrapolation rule for each time-series explicitly. Independent of the default or user-controlled I/E options, TIMES inter-/extrapolates (using the standard algorithm) all cost parameters in the objective function to the individual years of the model as part of calculating the annual cost details (see section 3.1.1.3 below).

The possibility of controlling interpolation on a time-series basis improves the independence between the years found in the primary database and the data actually used in the individual runs of a TIMES model. In this way the model is made more flexible with respect to running scenarios with arbitrary model years and period lengths, while using basically the very same input database.
3.1.1.1 Inter/extrapolation options

The TIMES interpolation/extrapolation facility provides both a default I/E method for all time-series parameters, and options for the user to control the interpolation and extrapolation of each individual time series (Table 6). The option 0 does not change the default behavior. The specific options that correspond to the default methods are 3 (the standard default) and 10 (alternative default method for bounds and RHS parameters).

Non-default interpolation/extrapolation can be requested for any parameter by providing an additional instance of the parameter with an indicator in the YEAR index and a value corresponding to one of the integer-valued Option Codes (see Table 6 and example below). This control specification activates the interpolation/extrapolation rule for the time series, and is distinguished from actual time-series data by providing a special control label ('0') in the YEAR index. The particular interpolation rule to apply is a function of the Option Code assigned to the control record for the parameter. Note that for log-linear interpolation the Option Code indicates the year from which the interpolation is switched from standard to log-linear mode. TIMES user shell(s) will provide mechanisms for imbedding the control label and setting the Option Code through easily understandable selections from a user-friendly drop-down list, making the specification simple and transparent to the user.

The enhanced interpolation/extrapolation facility provides the user with the following options to control the interpolation and extrapolation of each individual time series:

- Interpolation and extrapolation of data in the default way as predefined in TIMES. This option does not require any explicit action from the user.
- No interpolation or extrapolation of data (only valid for non-cost parameters).
- Interpolation between data points but no extrapolation (useful for many bounds). See option codes 1 and 11 in Table 2 below.
- Interpolation between data points entered, and filling-in all points outside the interpolation window with the EPS (zero) value. This can useful for e.g. the RHS of equality-type user constraints, or bounds on future investment in a particular instance of a technology. See option codes 2 and 12 in Table 2 below.

</tr>
</tbody>
</table>
• Forced interpolation and extrapolation throughout the time horizon. Can be useful for parameters that are by default not interpolated. See option codes 3, 4, and 5 as well as 14 and 15 in Table 2 below.

• Log-linear interpolation beyond a specified data year, and both forward and backward extrapolation outside the interpolation window. Log-linear interpolation is guided by relative coefficients of annual change instead of absolute data values.

Migration means that data points are interpolated and extrapolated within each period but not across periods. This method thus migrates any data point specified for other than milestone year to the corresponding milestone year within the period, so that it will be effective in that period.

Log-linear interpolation means that the values in the data series are interpreted as coefficients of annual change beyond a given YEAR. The YEAR can be any year, including modelyears. The user only has to take care that the data values in the data series correspond to the interpretation given to them when using the log-linear option. For simplicity, however, the first data point is always interpreted as an absolute value, because log-linear interpolation requires at least one absolute data point to start with.

3.1.1.2 Default inter/extrapolation

The standard default method of inter-/extrapolation corresponds to the option 3, which interpolates linearly between data points, while it extrapolates the first/last data point constantly backward/forward. This method, full interpolation and extrapolation, is by default applied to most TIMES time series parameters. However, the parameters listed in Table 7 are by default NOT inter/extrapolated in this way, but have a different default method.

3.1.1.3 Interpolation of cost parameters

As a general rule, all cost parameters in TIMES are densely interpolated and extrapolated. This means that the parameters will have a value for every single year within the range of years they apply, and the changes in costs over years will thus be accurately taken into account in the objective function. The user can use the interpolation options 1–5 for even cost parameters. Whenever an option is specified for a cost parameter, it will be first sparsely interpolated/extrapolated according to the user option over the union of modelyear and datayear, and any remaining empty data points are filled with the EPS value. The EPS values will ensure that despite the subsequent dense interpolation the effect of user option will be preserved to the extent possible. However, one should note that due to dense interpolation, the effects of the user options will inevitably be smoothed.

3.1.1.4 Examples of using I/E options

Example 1:

Assume that we have three normal data points in a FLO_SHAR data series:

\[
\begin{align*}
FLO\_SHAR('REG','1995','PRC1','COAL','IN\_PRC1','ANNUAL','UP') & = 0.25; \\
FLO\_SHAR('REG','2010','PRC1','COAL','IN\_PRC1','ANNUAL','UP') & = 0.12; \\
FLO\_SHAR('REG','2020','PRC1','COAL','IN\_PRC1','ANNUAL','UP') & = 0.05; \\
\end{align*}
\]

FLO_SHAR is by default NOT interpolated or extrapolated in TIMES. To force interpolation/extrapolation of the FLO_SHAR parameter the following control option for this data series should be added:

\[
FLO\_SHAR('REG','0','PRC1','COAL','IN\_PRC1','ANNUAL','UP') = 3;
\]
Example 2:

Assume that we define the following log-linear I/E option for a FLO_SHAR data series:

\[
\text{FLO\_SHAR('REG','0','PRC1','COAL','IN\_PRC1','ANNUAL','UP')} = 2005;
\]

This parameter specifies a log-linear control option with the value for the threshold YEAR of log-linear interpolation taken from 2005. The option specifies that all data points up to the year 2005 should be interpreted normally (as absolute data values), but all values beyond that year should be interpreted as coefficients of annual change. By using this interpretation, TIMES will then apply full interpolation and extrapolation to the whole data series. It is the responsibility of the user to ensure that the first data point and all data points up to (and including) the year 2005 represent absolute values of the parameter, and that all subsequent data points represent coefficients of annual change. Using the data of the example above, the first data point beyond 2005 is found for the year 2010, and it has the value of 0.12. The interpretation thus requires that the maximum flow share of COAL in the commodity group IN\_PRC1 is actually meant to increase by as much as 12% per annum between the years 1995 and 2010, and by 5% per annum between 2010 and 2020.
3.1.1.5 Applicability

All the enhanced I/E options described above are available for all TIMES time-series parameters, excluding PRC_RESID and COM_BPRICE. PRC_RESID is always interpolated, as if option 1 were used, but is also extrapolated forwards over TLIFE when either I/E option 5 or 15 is specified. COM_BPRICE is not interpolated at all, as it is obtained from the Baseline solution. Moreover, the I/E options are not applicable to the integer-valued parameters related to the SHAPE and MULTI tables, which are listed in Table 8.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>NCAP_AFM</td>
<td>Parameter value is a discrete numbers indicating which MULTI curve should be used, and not a time series datum.</td>
</tr>
<tr>
<td>NCAP_FOMM</td>
<td></td>
</tr>
<tr>
<td>NCAP_FSUBM</td>
<td></td>
</tr>
<tr>
<td>NCAP_FTAXM</td>
<td></td>
</tr>
<tr>
<td>COM_ELASTX</td>
<td></td>
</tr>
<tr>
<td>FLO_FUNCX</td>
<td></td>
</tr>
<tr>
<td>NCAP_AFX</td>
<td>Parameter value is a discrete number indicating which SHAPE curve should be used, and not a time series datum.</td>
</tr>
<tr>
<td>NCAP_FOMX</td>
<td></td>
</tr>
<tr>
<td>NCAP_FSUBX</td>
<td></td>
</tr>
<tr>
<td>NCAP_FTAXX</td>
<td></td>
</tr>
</tbody>
</table>

Nonetheless, a few options are supported also for the extrapolation of the MULTI and SHAPE index parameters, as shown in Table 9. The extrapolation can be done either only inside the data points provided by the user, or both inside and outside those data points. When using the inside data points option, the index specified for any datayear is extrapolated to all modelyears (v) between that datayear and the following datayear for which the SHAPE index is specified. The extrapolation options are available for all of the SHAPE and MULTI parameters listed in Table 8.

<table>
<thead>
<tr>
<th>Option code</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;= 0 (or none)</td>
<td>No extrapolation (default)</td>
</tr>
<tr>
<td>1</td>
<td>Extrapolation between data points only</td>
</tr>
<tr>
<td>2</td>
<td>Extrapolation between and outside data points</td>
</tr>
<tr>
<td>11</td>
<td>Extrapolation between data points only, migration at ends</td>
</tr>
</tbody>
</table>

Example:
The user has specified the following two SHAPE indexes and a control option for extrapolation:

```
NCAP_AFX('REG', '0', 'PRC1') = 1;
NCAP_AFX('REG', '1995', 'PRC1') = 12;
NCAP_AFX('REG', '2010', 'PRC1') = 13;
```

In this case, all modelyears (v) between 1995 and 2010 will get the shape index 12. No extrapolation is done for modelyears (v) beyond 2010 or before 1995.
3.1.2 Inheritance and aggregation of timesliced input parameters

As mentioned before, processes and commodities can be modelled in TIMES on different timeslice levels. Some of the input parameters that describe a process or a commodity are timeslice specific, i.e. they have to be provided by the user for specific timeslices, e.g. the availability factor NCAP_AF of a power plant operating on a 'DAYNITE' timeslice level. During the process of developing a model, the timeslice resolution of some processes or even the entire model may be refined. One could imagine for example the situation that a user starts developing a model on an 'ANNUAL' timeslice level and refines the model later by refining the timeslice definition of the processes and commodities. In order to avoid the need for all the timeslice related parameters to be re-entered again for the finer timeslices, TIMES supports inheritance and aggregation of parameter values along the timeslice tree.

Inheritance in this context means that input data being specified on a coarser timeslice level (higher up the tree) are inherited to a finer timeslice level (lower down the tree), whereas aggregation means that timeslice specific data are aggregated from a finer timeslice level (lower down the tree) to a coarser one (further up the tree). The inheritance feature may also be useful in some cases where the value of a parameter should be the same over all timeslices, since in this case it is sufficient to provide the parameter value for the 'ANNUAL' timeslice which is then inherited to the required finer target timeslices.21

The TIMES pre-processor supports different inheritance and aggregation rules, which depend on the type of attribute. The main characteristics of the different inheritance and

<table>
<thead>
<tr>
<th>Inheritance rules</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direct inheritance</td>
<td>A value on a coarser timeslice is inherited by target timeslices below (in the timeslice tree), without changing the numeric values.</td>
</tr>
<tr>
<td>Weighted inheritance</td>
<td>A value on a coarser timeslice is inherited by target timeslices below (in the timeslice tree) by weighting the input value with the ratio of the duration of the target timeslices to the duration of the coarser timeslice. Example: Parameter COM_FR.</td>
</tr>
<tr>
<td>No inheritance</td>
<td>Absolute bound parameters specified on a coarser timeslice level than the target timeslice level are not inherited. Instead a constraint summing over related variables on the finer timeslices is generated, e.g. an annual ACT_BND parameter specified for a process with a 'DAYNITE' process timeslice level (prc_tsl) leads to a constraint (EQ_ACTBND) with the summation over the activity variables on the 'DAYNITE' level as LHS term and with the bound as RHS term.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Aggregation rules</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard aggregation</td>
<td>The values specified on finer timeslices are aggregated to the target timeslice being a parent node in the timeslice tree by summing over the values on the finer timeslices.</td>
</tr>
<tr>
<td>Weighted aggregation</td>
<td>The values specified for finer timeslices are aggregated to the target timeslice being a parent node in the timeslice tree by summing over the weighted values on the finer timeslices. The ratios of the duration of the finer timeslices to the duration of the target timeslice serve as weighting factors.</td>
</tr>
</tbody>
</table>

21 The term target timeslice level or target timeslice is used in the following as synonym for the timeslice level or timeslices which are required by the model generators depending on the process or commodity timeslice resolution (prc_tsl and com_tsl respectively).
aggregation rules are summarised in Table 10. The specific rules applied to each individual parameter are listed in the detailed reference Table 13 further below.

The different aggregation rules are illustrated by examples in Figure 9. It should be noted that if input data are specified on two timeslice levels different from the target level, then especially the weighted inheritance/aggregation method may lead to incorrect results. Therefore, at least for the parameters where weighted methods are applied, it is recommended to provide input data only for timeslices on one timeslice level. However, for parameters that are directly inherited, specifying values at multiple levels may sometimes be a convenient way to reduce the amount of values to be specified.

Bound parameters are in most cases not levelized by inheritance, only by aggregation. Exceptions to this rule are the relative type bound parameters NCAP_AF and FLO_SHAR, which are inherited by the target timeslices. One should also notice that, due to levelization, fixed bounds that are either inherited or aggregated to the target timeslice level will always override any upper and lower bounds simultaneously specified.

Bound parameters are in most cases not levelized by inheritance, only by aggregation. Exceptions to this rule are the relative type bound parameters NCAP_AF and FLO_SHAR, which are inherited by the target timeslices. One should also notice that, due to levelization, fixed bounds that are either inherited or aggregated to the target timeslice level will always override any upper and lower bounds simultaneously specified.

Note that as an exception, for NCAP_AF direct inheritance and aggregation will be disabled if any values are specified at the process timeslice level. However, this may be circumvented by using NCAP_AFS for defining the values at process timeslices.

Figure 9: Inheritance and aggregation rules for timeslice specific parameters in TIMES
3.1.3 Overview of user input parameters

A list of all user input parameters is given in Table 13. In order to facilitate the recognition by the user of to which part of the model a parameter relates the following naming conventions apply to the prefixes of the parameters (Table 11).

Table 11: Naming conventions for user input parameters

<table>
<thead>

| COM_ELASTX  
|(r,datayear,c,bd)| COM_ELAST | Integer scalar $[1,999]$; default value: none  
Default extrapolation: MIG | Provided when shaping of elasticity based upon demand level is desired.  
Note: Shape index 1 is reserved for constant 1. | Shape index for the elasticity of demand | Affects the demand elasticities applied in EQ_OBJELS |
| COM_FR  
|(r,datayear,c,s)| COM_PROJ, com_ts, com_tsl, RTCS_TSFR | Decimal fraction $[0,1]$; default value: timeslice duration (G_YRFR)  
Default i/e: STD | Only applicable to demand commodities (com_type = 'DEM').  
Affects timeslice resolution at which a commodity is tracked (RTCS_TSFR), and thereby may affect when a process cannot operate (rtps_off).  
Weighted inheritance. Weighted aggregation. | Fraction of the annual demand (COM_PROJ) occurring in timeslice $s$; describes the shape of the load curve. | Applied to the annual demand (COM_PROJ) as the RHS of the balance equation (EQ(I)_COMBAL). Enters the peaking equation (EQ_PEAK), if a peaking commodity. Applied when setting the upper bound of an elastic demand step (VAR_ELAST). |
| COM_IE  
|(r,datayear,c,s)| | Decimal fraction $(0,\infty)$; default value: 1  
Default i/e: STD | Direct inheritance. Weighted aggregation. | Infrastructure or transmission efficiency of a commodity. | Overall efficiency applied to the total production of a commodity in the commodity balance equation (EQ(I)_COMBAL). |
| COM_PKFLX  
|(r,datayear,c,s)| com_peak, com_pkts, COM_PKRSV, FLO_PKCOI | Scalar $[open]$; default value: none  
Default i/e: STD | Direct inheritance. Weighted aggregation. | Difference between the average demand and the peak demand in timeslice $s$, expressed as fraction of the average demand. | Applied to the total consumption of a commodity to raise the capacity needed to satisfy the peaking constraint (EQ_PEAK). |
| COM_PKRSV  
<p>|(r,datayear,c)| com_peak, com_pkts, | Scalar $[0,\infty)$; | Peak reserve margin as fraction of peak | | Applied to the total consumption of a |</p>

\(^{23}\) Indexes refer to the parameters used in the model. 

\(^{24}\) Related sets or parameters provide additional context or dependencies for the input parameters. 

\(^{25}\) Units, ranges, and default values are crucial for specifying the input parameters within the model. 

\(^{26}\) Instances determine how the input parameters are used within the model, considering special conditions if applicable. 

\(^{27}\) Affected equations or variables list the specific parts of the model that are influenced by the input parameters.

3.2 Internal parameters

Table 14 gives an overview of internal parameters generated by the TIMES preprocessor. Similar to the description of the internal sets, not all internal parameters used within TIMES are discussed. The list given in Table 14 focuses mainly on the parameters used in the preparation and creation of the equations in Chapter 6. In addition to the internal parameters listed here, the TIMES preprocessor computes additional internal parameters which are either used only as auxiliary parameters being valid only in a short section of the code or which are introduced to improve the performance of the code regarding computational time.

Table 14: Internal parameters in TIMES

<table>

</tr>
<tr>
<td>RS_UCS (r,s,side)</td>
<td>Applied in timeslice-dynamic user constraints, to refer to the previous timeslice in the same cycle.</td>
<td>Lead from previous timeslice in the same cycle under the parent timeslice.</td>
</tr>
<tr>
<td>RTP_FFCX (r,v,t,p,cg,c,cg)</td>
<td>The efficiency parameter $\text{COEF_PTRAN}$ is multiplied by the factor $(1+\text{RTP_FFCX})$. Enters $\text{EQ_PTRANS}$ equation.</td>
<td>Average SHAPE multiplier of the parameter $\text{FLO_FUNC}$ and $\text{FLO_SUM}$ efficiencies in the $\text{EQ_PTRANS}$ equation in the period $(t)$ for capacity with vintage period $(v)$. The SHAPE curve that should be used is specified by the user parameter $\text{FLO_FUNCX}$. The SHAPE feature allows to alter technical parameter given for the vintage period as a function of the age of the installation.</td>
</tr>
<tr>
<td>Internal parameter(^{31}) (Indexes)</td>
<td>Instances (Required / Omit / Special conditions)</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>-----------------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>RTCS_TSFR ((r,t,c,s,ts))</td>
<td>Defined for each commodity with COM_FR. Applied to flow variables in all equations in order to take into account cases where some of the variables may be defined at a different timeslice level than the level of the equation.</td>
<td>The effective handling of timeslice aggregation/disaggregation. If ts is below s in the timeslice tree, the value is 1, if s is below ts the value is COM_FR(r,s) / COM_FR(r,ts) for demand commodities with COM_FR given and G_YRFR(r,s) / G_YRFR(r,ts) for all other commodities. The parameter is used to match the timeslice resolution of flow variables (VAR_FLO/VAR_IRE) and commodities. RTCS_TSFR is the coefficient of the flow variable, which is producing or consuming commodity c, in the commodity balance of c. If timeslice s corresponds to the commodity timeslice resolution of c and timeslice ts to the timeslice resolution of the flow variable two cases may occur: The flow variables are on a finer timeslice level than the commodity balance: in this case the flow variables with timeslices s being below ts in the timeslice tree are summed to give the aggregated flow within timeslice ts. RTCS_TSFR has the value 1. The flow variables are on coarser timeslice level than the commodity balance: in this case the flow variable is split-up on the finer timeslice level of the commodity balance according to the ratio of the timeslice duration of s to ts: RTCS_TSFR has the value = COM_FR(r,s) / COM_FR(r,s1) for demand commodities and G_YRFR(r,s) / G_YRFR(r,s1) otherwise. When COM_FR is used, the demand load curve is moved to the demand process. Thus, it is possible to model demand processes on an ANNUAL level and ensure at the same time that the process follows the given load curve COM_FR.</td>
</tr>
<tr>
<td>SALV_DEC ((r,v,p,k,\lnot l))</td>
<td>For those technologies with salvage costs incurred after the model horizon the contribution to the objective function.</td>
<td>Salvage proportion of decommissioning costs made at period v with commissioning year k.</td>

3.3 Report parameters

3.3.1 Overview of report parameters

The parameters generated internally by TIMES to document the results of a model run are listed in Table 15. These parameters can be imported into the VEDA-BE tool for further result analysis. They are converted out of the GDX file via the gdx2veda GAMS utility into a VEDA-BE compatible format according to the file times2veda.vdd. Note that some of the results are not transferred into parameters, but are directly accessed through the times2veda.vdd file (levels of commodity balances and peaking equation, total discounted value of objective function). The following naming conventions apply to the prefixes of the report parameters:

- CST_: detailed annual undiscounted cost parameters; note that also the costs of past investments, which are constants in the objective function, are being reported;
- PAR_: various primal and dual solution parameters;
- EQ(l)_: directly accessed GAMS equation levels/marginals
- REG_: regional total cost indicators.

Table 15: Report parameters in TIMES

<tbody>
<tr>
<td>AGG_OUT (r,t,c,s)</td>
<td>VAR_FOut</td>
<td>Commodity production by an aggregation process: Production of commodity (c) in period (t) and timeslice (s) from other commodities aggregated into c.</td>
</tr>
<tr>
<td>CAP_NEW (r,v,p,t,uc_n)</td>
<td>Cap_New</td>
<td>Newly installed capacity and lumpsum investment by vintage and commissioning period: New capacity and lumpsum investment of process (p) of vintage (v) commissioned in period (t).</td>
</tr>
<tr>
<td>CM_RESULT (c,t)</td>
<td>VAR_Climate</td>
<td>Climate module results for the levels of climate variable (c) in period (t).</td>
</tr>
</tbody>
</table>

---

<sup>32</sup> GDX stands for GAMS Data Exchange. A GDX file is a binary file that stores the values of one or more GAMS symbols such as sets, parameters variables and equations. GDX files can be used to prepare data for a GAMS model, present results of a GAMS model, store results of the same model using different parameters etc. They do not store a model formulation or executable statements.

<sup>33</sup> The use of the gdx2veda tool together with the times2veda.vdd control file and the VEDA-BE software are described in Part V.

<sup>34</sup> First row: parameter name; second row (in brackets): the index domain, for which the parameter is defined.

3.3.3 The levelized cost reporting option

As indicated in Table 15 above, the reporting of levelized costs for each process can be requested by setting the option RPT\_OPT('NCAP', '1'). The results are stored in the VEDA-BE \texttt{Var\_NcapR} result attribute, with the qualifier 'LEVCOST' (with a possible system label prefix).

The levelized cost calculation option looks to weight all the costs influencing the choice of a technology by TIMES. It takes into consideration investment, operating, fuel, and other costs as a means of comparing the full cost associated with each technology.
Levelized cost can be calculated according to the following general formula:

\[
LEC = \sum_{t=1}^{n} \frac{IC_t}{(1 + r)^{t-1}} + OC_t + \sum_i FC_{i,t} + FD_{i,t} + \sum_j ED_{j,t} - \sum_k BD_{k,t} - \sum_{m,t} MO_m \times (1 + r)^{-0.5} \]

where

- \( r \) = discount rate (e.g. 5%)
- \( IC_t \) = investment expenditure in (the beginning of) year \( t \)
- \( OC_t \) = fixed operating expenditure in year \( t \)
- \( VC_t \) = variable operating expenditure in year \( t \)
- \( FC_{i,t} \) = fuel-specific operating expenditure for fuel \( i \) in year \( t \)
- \( FD_{i,t} \) = fuel-specific acquisition expenditure for fuel \( i \) in year \( t \)
- \( ED_{j,t} \) = emission-specific allowance expenditure for emission \( j \) in year \( t \) (optional)
- \( BD_{k,t} \) = revenues from by-product \( k \) in year \( t \) (optional; see below)
- \( MO_{m,t} \) = output of main product \( m \) in year \( t \)

The exponent \( t-0.5 \) in the formula indicates the good practice of using mid-year discounting for continuous streams of annual expenditures.

In TIMES, the specific investment, fixed and variable O&M costs and fuel-specific flow costs are calculated directly from the input data. However, for the fuel acquisition prices, emission prices and by-product prices, commodity marginals from the model solution are used. All the unit costs are multiplied by the corresponding variable levels as given by the model solution: investment cost and fixed operating costs are multiplied by the amounts of capacity installed / existing, variable operation costs by the activity levels, and fuel-specific costs by the process flow levels. Mid-year discounting can also be activated.

The outputs of the main products are taken from the flow levels of the commodities in the primary group (PG) of the process. An exception is CHP processes, for which the electricity output is considered the sole main output, and heat is considered as a by-product.

Options for variants of levelized cost reporting:

1. Do not include emission prices or by-product revenues in the calculation (RPT_OPT(‘NCAP,’1’) = –1):

   In this option emission prices are omitted from the calculation, in accordance with the most commonly used convention for LEC calculation. Consequently, any by-product revenues need to be omitted as well, because if emissions have prices, the by-product prices in the solution would of course be polluted by those prices, and thus it would be inconsistent to use them in the calculation. Instead, in this case any amount of by-product energy produced by ELE, CHP and HPL processes is indirectly credited by reducing the fuel-specific costs in the calculation to the fraction of the main output in the total amount of energy produced.
2. **Include both emission prices and by-product revenues in the calculation**
   \( \text{RPT\_OPT('NCAP','1') = 1} \):
   In this option both emission prices and by-product revenues are included in the calculation. The levelized cost thus represents the unit cost after subtracting the levelized value of all by-products from the gross value of the levelized cost. This approach of crediting for by-products in the LEC calculation has been utilized, for example, in the IEA *Projected Costs of Generating Electricity* studies.

3. **Include not only emission prices and by-product revenues, but also the revenues from the main product in the calculation** \( \text{RPT\_OPT('NCAP','1') = 2} \):
   This option is similar to option (2) above, but in this case all product revenues are included in the calculation, including also the peak capacity credit from the TIMES peaking equation (when defined). The calculated LEC value thus represents the levelized net unit cost after subtracting the value of all products from the gross levelized cost. For competitive new capacity vintages, the resulting levelized cost should in this case generally be **negative**, because investments into technologies that enter the solution are normally profitable. For the marginal technologies the levelized cost can be expected to be very close to zero. Only those technologies that have been in some way forced into the solution, e.g. by specifying lower bounds on the capacity or by some other types of constraints, should normally have a positive levelized cost when using this option.

In the TIMES calculation, the expenditures for technology investments and process commodity flows include also taxes minus subsidies, if such have been specified. The levelized costs are calculated by process vintage, but only for new capacity vintages, as for them both the full cost data influencing technology choice and the operating history starting from the commissioning date are available, which is rarely the case for existing vintages.
4 Usage notes on special types of processes

4.1 Combined heat and power

4.1.1 Overview

Cogeneration power plants or combined heat and power plants (CHP) are plants that consume one or more commodities and produce two commodities, electricity and heat. One can distinguish two different types of cogeneration power plants according to the flexibility of the outputs, a back-pressure turbine process and a pass-out turbine process.

Back-pressure turbines are systems where the ratio of heat production to electricity production is fixed, and the electricity generation is therefore directly proportional to the heat generation. Pass-out turbines are systems where the ratio of heat production to electricity production is flexible, usually having a minimum value of zero and a maximum value usually in the range of 0.8–3 (but can be even smaller or larger).

However, both types of CHP systems often additionally support so-called reduction operation, where the turbine can be by-passed, whereby all the steam is directed to a heat exchanger for producing heat. As a result, in a back-pressure turbine system, the ratio of heat production to electricity production may in such systems vary from the fixed value to infinity, and in a pass-out turbine system it may vary from zero to infinity.

All these different cases are illustrated in Figure 10 below, which shows the relations between heat and electricity production in different modes of a flexible CHP system, of which the back-pressure turbine system is a special case. Taking into account that thermal power plants usually have a minimum stable operation level, the operating area of the fixed back-pressure turbine system is represented by the line E–F in the Figure. The corresponding operating area of a pass-out turbine system (without reduction operation) is represented by the polygon A–B–F–E. In some cases the turbine characteristics require a minimum level of heat production in proportion to electricity, and with such a constraint the feasible operating area is reduced to C–D–F–E. Finally, with a reduction operation the feasible operating area is expanded to the polygon C–D–F–H–G–E in the Figure. Similarly, the operating area of a back-pressure turbine system with a reduction operation capability would be expanded to E–F–H–G.

Denoting the electrical efficiency in the full condensing mode (point B) by $\eta_B$, the total efficiency in the full CHP mode (point F) by $\eta_F$, the heat-to-power ratio (inverse slope of line E–F) by $R$, and the slope of the iso-fuel line (B–F) by $S$, we can easily write the relations between these as follows:

$$\eta_B = \frac{\eta_F \times (1 + R \times S)}{1 + R}$$

$$\eta_F = \frac{\eta_B \times (1 + R)}{1 + R \times S}$$

$$S = \frac{\eta_B \times (1 + R) - \eta_F}{\eta_F \times R}$$

The core TIMES parameters for modeling the CHP attributes are listed in Table 17.
4.1.2 Defining CHP attributes in TIMES

4.1.2.1 Back-pressure turbine systems

For modelling a fixed back-pressure turbine system in TIMES, the following approach is recommended:

- Define the PCG of the process to consist of both the electricity and heat output commodities (using the set prc_actunt);
- Define the process type to be CHP (using the set prc_map);
- Use the electrical output as the basis of the process activity, and choose the capacity unit accordingly (using the parameter PRC_CAPACT);
- Define the process electrical efficiency (by using the parameter ACT_EFF);

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

* Only taken into account for processes defined to be of type CHP with the set prc_map.

Figure 10: Illustration of basic CHP characteristics supported in TIMES.
• Define the process cost parameters accordingly; for example, specify the investment and fixed O&M costs per electrical capacity;
• Define the fixed heat-to-power ratio (using the parameter NCAP_CHPR);
• Optionally, define also a maximum annual utilization factor considering the typical optimal sizing of CHP plants in proportion to the heat demand in the heat network represented (using the parameter NCAP_AFA);
• Optionally, define a minimum stable operation level (using ACT_MINLD).

All the input data specifications mentioned above should be quite straightforward. Note that the NCAP_CEH parameter is not needed at all in the fixed turbine case.

For back-pressure turbine technologies that have a reduction operation capability, one can enable the reduction option by adding to the process a third output of a dummy commodity, which is of type NRG and has a limit type 'N', and is also a member of the PCG. The model generator will automatically assign such a dummy output to the reduction operation, and will adjust the process transformation equation accordingly.

4.1.2.2 Pass-out turbine systems

For modelling a flexible pass-out turbine system in TIMES, the following approach is recommended (but see additional remarks below):
• Define the PCG of the process to consist of both the electricity and heat output commodities (using the set prc_actunt);
• Define the process type to be CHP (using the set prc_map);
• Use the maximum electrical output as the basis of the process activity, and choose the capacity unit accordingly (using the parameter PRC_CAPACT);
• Define the process electrical efficiency according to the maximum electrical efficiency (at point D in Figure 10), by using the parameter ACT_EFF;
• Define the process cost parameters accordingly, for example, specify the investment and fixed O&M costs per unit of electrical capacity;
• Define the maximum heat-to-power ratio (excluding any reduction operation), and optionally also the minimum heat-to-power ratio (using the parameter NCAP_CHPR);
• Define the slope S of the iso-fuel line (the line B–F in Figure 10) by specifying NCAP_CEH=S (where −1 < S < 0, as in Figure 10);
• Optionally, define also a maximum annual utilization factor considering the typical optimal sizing of CHP plants in the heat network represented (using the parameter NCAP_AFA and/or NCAP_AFC);
• Optionally, define a minimum stable operation level (using ACT_MINLD).

Again, the specifications should be quite straightforward. The slope S of the iso-fuel line represents the amount of electricity lost per heat gained. In the example of Figure 10, the inverse of the slope has the value 7 and so one would define NCAP_CEH = −1/7.

The activity remains constant over the iso-fuel line, but the electricity output varies when moving along it. Maximum electrical output is thus usually the most convenient quantity along this line for defining the basis of the process activity and capacity. This choice should then be consistently reflected in the input data (see Table 18).
Alternatively, if it would seem more convenient to define both the condensing mode efficiency and the full CHP efficiency, that can be done by using the parameters NCAP_CDME (condensing mode efficiency) and NCAP_BPME (back-pressure mode efficiency). When these two parameters are used, the NCAP_CEH and ACT_EFF parameters should then not be used at all. The activity will in this alternative approach always represent the electricity output in condensing mode.

For pass-out turbine technologies that have a reduction operation capability, one can enable the reduction option by adding to the process a third output of a dummy commodity, which is of type NRG and has a limit type ‘N’, and is also a member of the PCG. The model generator will automatically assign such a dummy output to the reduction operation, and will adjust the process transformation equation accordingly.

4.1.2.3 Alternative choices for defining the activity basis
As indicated above, the recommended basis of the activity of a CHP technology is the maximum electricity output, because the available technology data is usually best suited for using the electricity output as the basis for the activity. However, also the total energy output in full CHP mode can be used as the basis for the activity, should that be a more convenient way of defining the process data.

The below summarizes the different options modelling CHP processes according to the choice of the main efficiency parameters. Note that the cases with \(-1 < \text{CEH} \leq 0\) and \(0 \leq \text{CEH} < 1\) are identical when there is no lower bound for NCAP_CHPR specified.

4.2 Inter-regional exchange processes

4.2.1 Structure and types of endogenous trade

In TIMES, the inter-regional trading structure of a given commodity basically consists of one or several exchange processes (called IRE processes), each of which defines a portion of the trading network for the commodity. The individual sub-networks can be linked together through common intermediating regions. As an example, electricity trade can be conveniently described by bi-lateral exchange processes (see Figure 12). But bi-lateral trading between all pairs of regions may become onerous in terms of data and model size. It is therefore useful to consider the other trade structure of TIMES, called multi-lateral trade, where regions trade with a common market (Figure 11). For either structure, the topology of the trading possibilities are all defined via the set top Ire of quintuples \{r1,c1,r2,c2,p\}, where r1, r2 are the exporting and importing regions respectively, c1, c2 are the names of the traded commodity in regions r1 and r2 respectively, and p is the process identifier. Process p is a process in both regions. It has to be defined only once, but one can add parameters to it in both regions (e.g. costs, bounds, etc.). Nearly every piece of data in TIMES has to be assigned to a region.

TIMES provides considerable flexibility in the definition of trading structures. Each sub-network defined for a single exchange process can have the general structure shown in Figure 11. A trading structure that involves both several supply (export) regions and several demand (import) regions cannot be defined without introducing an intermediating 'market' region (RM). Whenever such an intermediate region is defined between (at least) two different regions, the model generator will assume that the structure is actually meant to ignore the intermediate node-region shown in Figure 11, by generating a single trade

![Figure 11. General structure of the pair-wise specification of the trading sub-network allowed in TIMES for a single exchange process.](image-url)
balance equation directly between all the export and all the import flows. If the intermediate step should nonetheless be included, for example, to reflect a physical market hub in the region $R_M$, this can be accomplished by dividing the sub-network into two parts, by using two exchange processes. Consequently, depending on the user’s choice, the trading relationships shown in Figure 11 can be modeled both with and without the intermediate transportation step through the market region.

The general structure allowed for the trading sub-networks can be further divided into four cases, which will be discussed below in more detail:

- **Case 1:** Bi-lateral trading.
- **Case 2:** Unidirectional trade from some export regions into a single importing region
- **Case 3:** Multi-directional trade from a single export region to several importing regions
- **Case 4:** General multi-lateral trading structure

**Trading without need for explicit marketplace definition**

Cases 1, 2 and 3 fall in this category. Bi-lateral trade takes place between pairs of regions. An ordered pair of regions together with an exchange process is first identified, and the trade through the exchange process is balanced between these two regions. Whatever amount is exported from region $i$ to region $j$ is imported by region $j$ from region $i$ (possibly with an adjustment for transportation losses). The basic structure is shown in Figure 12. Bi-lateral trading can be fully described in TIMES by specifying the two pairwise connections in `top_ire`. The capacity and investment costs of the exchange process can be described individually for both regions. For Cases 2 and 3, the general structure of the trade relationships is shown in Figure 13. Also in these cases the definition of the trading structure is easy, because the relationships can be unambiguously described by pairwise `top_ire` specifications between two regions.

**Trading based on marketplace**

Case 4 is covered by the generic structure shown in Figure 11. Trading occurs in this case between at least three regions, and involves both several exporting regions and several importing regions. In this type of trade, the commodity is ‘put on the market’ by each region participating in the supply side of the market and may be bought by any region participating in the demand side of the market. This case is convenient for global commodities such as emission permits or crude oil where the transportation cost from $R_i$ to

![Figure 12. Case 1: Bi-lateral trade (both $R_1$ and $R_2$ qualify as $R_M$).](image-url)
$R_i$ may be approximated by $\text{Cost}_i + \text{Cost}_j$ (rather than a more accurate cost such as $C_{ij}$). When the exact cost (or losses) are strictly dependent on the pair $i, j$ of trading regions, it may be more accurate to use bilateral trade.

In general, there are many different possibilities for defining the multi-lateral structure by using the pair-wise top_ire specifications. In order to comply with the structure allowed in TIMES, the user has to decide which of the regions represents the ‘marketplace’, i.e. is chosen to be the $R_M$ shown in Figure 11. Note that the market region will participate both in the supply and demand side of the market. The TIMES model generator automatically identifies this general type of trading on the basis of the top_ire topology defined by the user. Therefore, the user only needs to define the possible trading relationships between regions into the set top_ire. If there are $n$ supply regions and $m$ demand regions, the total number of entries needed in top_ire for defining all the trade possibilities is $n + m - 2$ (counting the market region to be included in both the supply and demand regions. Although the market region has to be defined to be an intermediate node in the structure, the model generator will actually not introduce any intermediate step between the export and import regions.

The timeslice levels of the traded commodity may be different in each region (as well as the commodity name). However, some appropriate common timeslice level must be chosen for writing the market balance equation. That common level is the level attached to the exchange process in the market region. In all other respects, the market region is not treated in any way differently from the other regions participating in the market. Nevertheless, the user can of course provide different data for the different regions, for example investment costs or efficiencies for the exchange process can be differentiated by region.

If the sets of supply and demand regions participating in the market should actually be disjoint, even in that case the user has to choose one of the regions to be used as the intermediate market region. The imports to or exports from the market region can then be switched off by using an IRE_XBND parameter, if that is considered necessary.
Remarks on flexibility

1. Any number of exchange processes can be defined for describing the total trade relationships of a single commodity (but see warning 1 below).

2. The names of traded commodities can be different in each region participating in the trade. In addition, also the import and export names of the traded commodities can be different (but see warning 2 below). This could be useful e.g. in the case of electricity, for which it is common to assume that the export commodity is taken from the system after grid transport, while the import commodity is introduced into the system before the grid.

3. Any number of commodities can be, in general imported to a region or exported from a region through the same process (but see warning 2 below).

Warnings

1. For each exchange process of any traded commodity, the total structure of the trading sub-network, as defined in top_ire, must comply with one of the basic structures supported by TIMES (Cases 1–4). If, for example, several bi-lateral trading relationships are defined for the same commodity, they should, of course, not be defined under the same process, but each under a different process.

2. If the export and import names for a market-based commodity (c) are different in the market region, no other commodities should be imported to the market region through the same exchange process as commodity c.

3. The model generator combines the trading relationships of a single process into a single market whenever there is an intermediate region between two different regions. If, however, the intermediate exchange step should be explicitly included in the model, the trading sub-network should be divided between two different exchange processes.

Example

Assume that we want to set up a market-based trading where the commodity CRUD can be exported by regions A, B, C, and D, and that it can be imported by regions C, D, E and F. First, the exchange process and marketplace should be defined. For example, we may choose (C,XP,CRUD) as the marketplace, where XP has been chosen to be the name of the exchange process (recall that process XP is declared only once but exists in all trading regions, possibly with different parameters). The trade possibilities can then be defined simply by the following six top_ire entries:

```
SET PRC / XP /;
SET TOP_IRE /
  A .CRUD .C .CRUD .XP
  B .CRUD .C .CRUD .XP
  D .CRUD .C .CRUD .XP
  C .CRUD .D .CRUD .XP
  C .CRUD .E .CRUD .XP
  C .CRUD .F .CRUD .XP
/;
```

To complete the RES definition needed for the exchange process, in addition only the set prc_actunt(r,p,c,u) needs be defined for the exchange process XP:
These definitions are sufficient for setting up of the market-based trade. Additionally, the user can, of course, specify various other data for the exchange processes, for example investment and distribution costs, efficiencies and bounds.

4.2.2 Input sets and parameters specific to trade processes

TIMES input SETs that have a special role in trade processes are the following:

- **top_ire(r1,c1,r2,c2,p):** For bi-lateral trade, unidirectional trade into a single destination region, and multidirectional trade from a single source region, **top_ire** should contain the corresponding entries from the exporting region(s) r1 to the importing region(s) r2. For market-based trade, **top_ire** must contain entries for each exporting region to the intermediate market region, and from the market region to each importing region. Each region may be both exporting and importing. One may thus force even a bi-lateral exchange to be modeled as market-based trade, by introducing an additional **top_ire** entry within the desired market region between the exported and imported commodity. Instead of two trade balance equations, only one market balance equation is then generated.

- **prc_aoff(r,p,y1,y2):** Override used to control in what years (not periods) a process is unavailable. This set is not specifically related to exchange processes. However, in the case of market-based trading it can be used to switch off the entire commodity market for periods that fall within the range of years given by **prc_aoff**. The market will be closed for all commodities exchanged through the process (p). If trading should be possible only between certain years, even multiple entries of **prc_aoff** can be specified.

All the **top_ire** specifications are handled for the user by the user shell (VEDA/ANSWER) according to the characterization of the trade processes.

Additional remarks:

1. Commodity type can be used as the primary group of IRE processes. All commodities of that type, traded through the process, will then be included in the PCG.
2. Topology entries are automatically created on the basis of IRE_FLOSUM and FLO_EMIS defined for IRE processes (the latter only for ENV commodities).
3. In any non-bilateral trade, the marketplaces are automatically set by the model generator for any trade that involves an intermediate region between two different regions for the same exchange process (p) and same commodity (c), or if there are multiple destination (importing) regions for the same exporting region.
4. In market-based trade with \( r \) as the market region, the import/export regions participating in the market consist of all those regions that import/export commodity \( c \) from/into region \( r \) through process \( p \) (as defined in top_ire). The market region \( r \) by itself always participates in the market both as an importing and exporting region. However, the imports/exports of commodity \( (c) \) to/from the market region \( (r) \) can be switched off by using an IRE_XBND parameter, if necessary.

**Input parameters**

Input parameters specific to inter-regional exchange processes are listed in Table 19.

<table>
<thead>
<tr>
<th>Attribute name (indexes)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IRE_FLO ((r1,y,c1,r2,c2,s2))</td>
<td>Coefficient that represents the efficiency of exchange from ( r1 ) to ( r2 ), inside an inter-regional process where both regions are internal. Note that separate IRE_FLOs are required for import and export. Default =1 for each top_ire direction specified. Time slice ( s2 ) refers to the region where the commodity arrives. Units: none</td>
</tr>
<tr>
<td>IRE_FLOSUM ((r,y,c1,s,ie,c2,io))</td>
<td>Special attribute to represent auxiliary consumption ((io = 'IN')), or production/emission ((io = 'OUT')) of commodity ( c2 ) due to the IMPort / EXPort (index ( ie )) of the commodity ( c1 ) in region ( r ) by an inter-regional process ( p ). It is a fixed FLO_SUM with (one of) the pcg in that region. These relate commodities on the same side of the process. Auxiliary flows can also be specified on the process activity, by setting ( c1 = 'ACT' ) in the IRE_FLOSUM parameter (or in a FLO_EMIS parameter).</td>
</tr>
<tr>
<td>IRE_BND ((r1,y,c,s,r2,ie,bd))</td>
<td>Bound on the total import/export (index ( ie )) into/from internal region ( r1 ), from/to region ( r2 ), where region ( r2 ) may be internal or external; ( c ) is the name of commodity in region ( r1 ). Default none.</td>
</tr>
<tr>
<td>IRE_XBND ((r,y,c,s,ie,bd))</td>
<td>Bound on total imports/exports of commodity ( c ) in region ( r ), to/from all destinations/sources, where ( r ) may be an internal or external region. (Default value: none)</td>
</tr>
<tr>
<td>IRE_CCVT ((r1,c1,r2,c2))</td>
<td>Conversion factor between commodity units, from unit of ( c1 ) in region ( r1 ) to unit of ( c2 ) in region ( r2 ), as part of inter-regional exchanges. Default = 1, when exchange permitted. Units: none.</td>
</tr>
<tr>
<td>IRE_TSCVT ((r1,s1,r2,s2))</td>
<td>A matrix that transforms timeslices of region ( r1 ) to region ( r2 ) as part of inter-regional exchanges, including both internal and external. Default value = 1 when exchange permitted. Units: none.</td>
</tr>
</tbody>
</table>

---

36 The indexing of auxiliary consumption flows or emissions of inter-regional exchange processes is illustrated in the figure below.

---

37 The equation EQ(l)_XBND may have an external regional as region index (bounding the import from one external regions to all other regions).
Remarks:

1. In market-based trading the IRE_FLO parameter is taken into account on the export side only (representing the efficiency from the export region to the common marketplace). By using this convention, any bi-lateral exchange can be represented by a fully equivalent market-based exchange simply by choosing one of the two regions to be the marketplace, and adding the corresponding entry to the set rpc_market(r,p,c). The efficiency of the exports from the market region itself to the marketplace should also be specified with an IRE_FLO parameter, when necessary (r1=r2=market region).

2. If the user wants to specify efficiency on the import side of a market-based exchange, this can be done by using an IRE_FLOSUM parameter on the import side.

3. Similarly to any other pair of regions, the total amount of commodity imported to a region from the commodity market can be constrained by the IRE_BND parameter, by specifying the market region as the export region. Correspondingly, the total amount of commodity exported from a supply region to the marketplace can be constrained by the IRE_BND parameter by specifying the market region as the import region.

4.2.3 Availability factors for trade processes

In TIMES, capacity by default bounds only the activity. However, with the NCAP_AFC / NCAP_AFCS attributes, one can bound the import / export flows instead. Capacity then also refers to the nominal maximum import (or export) capacity, e.g. the capacity of a transmission line in either direction. One can thus simultaneously bound the import and export flows by the same capacity but with different availabilities, which can be useful with bi-directional exchange links with different availabilities in the import/export direction. All these availability factors can be defined either on a desired timeslice level (NCAP_AFC), or on individual timeslices (NCAP_AFCS).

The rules for defining the availabilities for trade flows can be summarized as follows:

- If the import/export commodities are different (c1/c2): Use NCAP_AFC(c1) for bounding the import flow and NCAP_AFC(c2) for bounding the export flow, or use NCAP_AFC('NRG') for applying the same availability to both flows.
- If input=output=c, specifying either NCAP_AFC(c) or NCAP_AFC('NRG') alone applies to both imports and exports (unless the process type is DISTR, see Section 4.2.4 below). However, if they are both specified, then NCAP_AFC(c) applies to the import flow while NCAP_AFC('NRG') applies to the export flow.

Remarks:

1. As any process has only a single capacity variable, the availabilities specified for the import/export flows are always proportional to the same overall capacity.
2. Note that any the availability factors defined by NCAP_AFC are multiplied by any NCAP_AF/NCAP_AFS/NCAT_AFA value if defined for the same timeslice.
4.2.4 Notes on other attributes for trade processes

There are important limitations of using the parameters for standard processes for IRE processes. The most important limitations are summarized Table 20 with regard to the parameters with the prefixes 'ACT_', 'FLO_' and 'PRC_'. In addition, none of the CHP parameters, storage parameters (STG_*), or dispatching parameters (ACT_MINLD, ACT_UPS, ACT_CSTUP, ACT_LOSPL, ACT_CSTPL, ACT_TIME), can be used for IRE processes, and are ignored if used.

Table 20: Limitations of using standard process parameters for IRE processes.

</tbody>
</table>

Additional remarks with respect to inter-regional trade (IRE) processes:

- By using the process type indicator 'DISTR', the activity and capacity of an IRE process will be based on the import flow only, if the same commodity is both imported and exported. In this case also NCAP_AFC(c) will only apply to the import flow of c.
- In peaking equations, IRE processes are by default taken into account by having gross imports on the supply side and gross exports on the consumption side. By defining the IRE process as a member of the set PRC_PKNO, and also defining NCAP_PKCNT>0, only the net imports are taken into account on the supply side, which can be useful for regions having trade flows passing through the region.
4.3 Storage processes

4.3.1 Overview

The TIMES model generator provides tools for specifying the following types of storage processes:

- Standard timeslice storage (STG without additional storage type qualifier)
- Generalized timeslice storage (STG+STS)
- Day/night storage (STG+NST, or just NST if at ANNUAL level)
- Inter-period storage (STG+STK)

The process type indicator STG is automatically assigned also to all processes that have been defined to be of type STS, NST or STK, with the exception of ANNUAL level NST processes, which are implemented as normal processes (see Section 4.3.3 below). Therefore, the user only needs to specify one of {STG, STS, NST, STK} as the process type of a storage process.

In addition to the charged and discharged commodity, storage processes can also produce and consume auxiliary commodities (emissions, electricity, fuels, waste etc.). The flows of such auxiliary commodities can be defined to be proportional either to the activity, the main input flows, or the main output flows of the storage (see Section 4.3.5 below).

4.3.2 Timeslice storage

The standard timeslice storage operates within the timeslice cycles under the timeslice cycles of the level immediately above the process timeslice level. Consequently, the commodity charged can be only stored over the cycle of timeslices under a single parent timeslice, and not between timeslices under different parent timeslices. For example, a standard DAYNITE level storage can only store the charged commodity over the timeslices under one season, and not between seasons.

The activity of a timeslice storage represents the storage level, i.e. the amount of energy/material stored in the storage, measured at the beginning of each timeslice. However, one should note that for a DAYNITE level storage, the level of the activity variable for each timeslice is the actual storage level multiplied by the number of days under the parent timeslice, in the same way as the level of the activity variables for standard processes is the daily activity in that timeslice multiplied by the number of days under the parent timeslice.

If a storage technology is capable of storing energy for longer periods than over daily cycles, one may consider combining a SEASON/WEEKLY level storage process with a DAYNITE storage. However, a DAYNITE level storage may also be generalized to provide a storage capability between seasons, and even between periods, by using the generalized timeslice storage type qualifier 'STS' (and both 'STS' and 'STK', if the inter-period storage capability should be included). Because the same storage capacity can be utilized on all timeslice levels, the general storage process type may thus provide a somewhat improved modeling of a multi-cycle storage.
4.3.3 Day/Night storage

Day/Night storage (NST) is a timeslice storage, which can store energy over the day-night cycles, but not over weekly or seasonal cycles. In its basic functionality, an NST storage does not differ much from a standard timeslice storage, the main difference being that one can define the charging timeslices by specifying them in the set \texttt{prc_nstts}.

Day/Night storage processes that produce ANNUAL level demand commodities can be modeled either as genuine storage processes or as standard processes with a night storage capability. In both cases 'NST' should be specified as the process type. If the process itself is defined to operate at the DAYNITE level, the process will be a genuine storage process, but if it is defined to operate at the ANNUAL level, it will be a standard process. For any such night storage devices, the charging and discharging commodity may be different, as defined via the set \texttt{top}.

When the NST process \( p \) is a genuine storage process, the input set \texttt{prc_nstts}(r,p,s) may be used for defining the charging timeslices \( s \). Discharging can then only occur in timeslices other than the charging timeslices. Defining \texttt{prc_nstts} is required for all other genuine NST processes, except those serving an ANNUAL level demand, which can always discharge at the level of the demand, regardless of any \texttt{prc_nstts} defined.

In both types of NST storage, if the process is serving any ANNUAL level demand, the demand commodity is produced according to the load curve, while the charging can be optimized so that it occurs at night timeslices only. However, when the NST process is a normal process, it can be described in all other respects just as any other end-use technologies. For example, electric heating systems with accumulators can be described basically in the same way as direct electric heating systems, but with the additional night storage capability.

4.3.4 Inter-period storage

An inter-period storage process is able to store energy or material over periods. For example, a coal stockpile or a waste disposal site can be modeled as an inter-period storage. All inter-period storage processes should be defined to operate at the ANNUAL level, unless the generic timeslice process characterization (STS) is also specified.

The initial stock of an inter-period storage process can be specified by using the \texttt{STG_CHRG} parameter, which is interpolated such that it always includes the year at the beginning of the model horizon \( B(t1) - 1 \). The value of \texttt{STG_CHRG} in the year \( B(t1) - 1 \) is used as the initial stock for inter-period storage. The allocation of the initial stock between the process vintages that are available at the beginning of the model horizon is left to be optimized by the model.

The activity of an inter-period storage is measured at the end of each period. Therefore, either by setting a lower bound on the activity or on the process availability, the storage can be prevented from getting fully discharged during any period. However, as there is no explicit accounting of the salvage value of the remaining contents of an inter-period storage, it may also be considered reasonable to allow discharging the storage fully in the last period, for taking into account the value of the storage.
4.3.5 Auxiliary storage flows

Storage processes can have any amount of auxiliary input or output commodities, as long as they are distinct from the main storage commodity. The flows of the auxiliary commodities can only be defined to be fixedly proportional either to the activity, the main input flows, or the main output flows. The main flows of timeslice and inter-period storage processes are the flows of the charged and discharged commodities included in the set primary commodity group PCG of the process. In the day/night storage processes, the main flows consist of all commodities in the primary and shadow groups of the process (see documentation).

The relation between the auxiliary flows and the activity or main flows should be defined by using the PRC_ACTFLO and the FLO_FUNC parameters. For example, if the main storage flows of the process consist of the commodity 'STORED', and the auxiliary commodity is 'AUX', the auxiliary flow can be defined in the three following ways, corresponding to the cases where the auxiliary flow is proportional to the activity, the input flow, or the output flow, respectively:

\[
\text{PRC_ACTFLO}(r, t, p, 'AUX') \quad \text{! AUX proportional to activity}
\]
\[
\text{FLO_FUNC}(r, t, p, 'STORED', 'AUX', s) \quad \text{! AUX proportional to input flow}
\]
\[
\text{FLO_FUNC}(r, t, p, 'AUX', 'STORED', s) \quad \text{! AUX inversely proportional to output flow}
\]

These auxiliary storage flow relations have been implemented by adding a new TIMES equation EQ_STGAUX(r, v, t, p, c, s). As the auxiliary storage flows are represented by standard flow variables, any flow-related cost attributes and UC constraints can be additionally defined on these auxiliary flows. However, no transformation equations can be defined between any auxiliary storage flows. Therefore, if, for example, some auxiliary flows should also produce emissions, also these emissions should be defined on the basis of the activity or main flows, and not by defining a relation between the auxiliary flow and the emission flow. Consequently, it is required that all auxiliary commodity flows related to storage processes, whether energy, material, or emissions, are described by using the three types of relations shown above.

A concrete example where these enhancements to the storage processes can be very useful is the modeling of waste management, and, in particular, the modeling of landfilling of different types of waste. Using inter-period storage processes for this purpose makes it possible to conveniently incorporate e.g. the following features in the waste management model:

- Modeling of methane emissions from landfilling in a dynamic way by using first-order decay functions for the gradual waste decomposition (optionally with different rates of decay for different waste qualities);
- Modeling of other waste management and emission reduction options both before and after landfilling;
- Incorporating gate fees to landfill sites (by defining costs on an input-based auxiliary storage flow).
4.3.6 Input sets and parameters specifically related to storage processes

Input sets

There is only one TIMES input SETs specifically related to storage: prc_nstts. However, there are important storage-specific aspects related to each of the following input sets:

- **prc_map(r,prc_grp,p):** Defines the process as a storage process, where 
  prc_grp=STG/STS/NST/STK according to the desired storage type.

- **prc_actunt(r,p,CG,units_act):** Definition of the commodity/commodities in the 
  PCG, i.e. those that are stored. Set of quadruples such that the members of the 
  commodity group cg is used to define the charged and discharged commodity of 
  storage process p, with activity units units_act, in region r. If the charged and 
  discharged commodities are different, the group cg should preferably contain both 
  of them, but if the user shell does not allow that, the model generator will 
  automatically assign to the PCG any commodities on the shadow side that are of the 
  same type than those already in the PCG, and are not verified to be auxiliary 
  commodities. A commodity type can also be used as the primary group of storage 
  processes. All commodities of that type will then be included in the PCG.

- **top(r,p,c,io):** Definition of the charged (io=IN) discharged (io=OUT) and optional 
  auxiliary input/output commodities for storage process p in region r. The set 
  top_ire should thus first and foremost contain the input/output indicators for the 
  stored commodities defined by prc_actunt (see above), but should include also any 
  auxiliary input/output commodities assumed for the process. When the charged and 
  discharged commodity is the same, that commodity can optionally be defined only 
  as an input or only as an output, and in that case it will be connected to the 
  commodity balance equations either only on the production or only on the 
  consumption side, instead of being connected on both sides.

- **prc_nstts(r,p,s):** For genuine night storage process p in region r, defines the 
  timeslices s to be the charging timeslices, at which discharging cannot occur.

Remarks

In TIMES, the input (charge) and output (discharge) commodity of a storage process is 
usually the same commodity (input=output). When so, and this commodity is defined both 
as an input and an output of the process, the input and output flows will be taken into 
account in the commodity balance equations on different sides: the input on the 
consumption side, and the output on the production side.

However, in some cases this design has proven to be undesirable, because due to the 
nature of the storage processes, the input and output flows can usually be made arbitrarily 
large without affecting the storage operation or costs. That is so because the input flow may 
also by-pass the storage in the same timeslice or period, without being stored, and will then 
be directly converted into the output flow, without any costs or efficiency losses (unless 
STG_EFF is being used). Such arbitrary input/output flows can also make the total 
commodity production arbitrarily large, thereby rendering VAR_COMPRD a very 
unreliable measure of the size of the commodity market. This can be undesirable with
respect to various market-share constraints that are usually defined on the basis of the VAR_COMPRD values.

In order to avoid any arbitrary storage flows on the production or consumption side, the input/output flows can be defined to be both connected either on the production or consumption side, instead of being on different sides. This will prevent the undesirable impacts of such arbitrary flows. The desired side can be chosen by the user by defining the commodity only as an output (production side) or as an input (consumption side).

**Input parameters**

The TIMES input parameters that are specific to storage processes or have a specific functionality for storage processes are summarized in Table 21.

**Table 21: Specific TIMES parameters related to the modelling of storage processes.**

<table>
<thead>
<tr>
<th>Attribute name (indexes)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STG_CHRG (r,y,p,s)</td>
<td>Exogenous amount assumed to be charged into storage p, in timeslice s and year y. For timeslice storage this parameter can be specified for each period, while for inter-period storage this parameter is only taken into account for the first period, to describe the initial content of the storage at the beginning of the model horizon. Units: Unit of the storage input flow.</td>
</tr>
<tr>
<td>STG_EFF (r,y,p)</td>
<td>Coefficient that represents the storage efficiency of a storage process p in region r. Applied at the commodity balance to the output flow.</td>
</tr>
<tr>
<td>STG_LOSS (r,y,p,s)</td>
<td>Coefficient that represents the annual storage losses of a storage process p in region r, as a fraction of the (average) amount stored, corresponding to a storage time of one year. If the value specified is negative, the corresponding annual losses are interpreted as an annual equilibrium loss (under exponential decay).</td>
</tr>
<tr>
<td>STGIN_BND (r,y,p,c,s,bd)</td>
<td>Bound on the input flow of commodity c of storage process p in a timeslice s. Units: Unit of the storage input flow. (Default value: none)</td>
</tr>
<tr>
<td>STGOUT_BND (r,y,p,c,s,bd)</td>
<td>Bound on the output flow of commodity c of storage process p in a timeslice s. Units: Unit of the storage input flow. (Default value: none)</td>
</tr>
<tr>
<td>FLO_FUNC (r,y,p,c1,c2,s)</td>
<td>Defines the ratio between the flow of commodity c2 and the flow of commodity c1, in timeslice s, in other words, an efficiency coefficient giving the flow of commodity c2 per one unit of flow of commodity c1. For storage processes, can be used for defining amount of discharge in c2 per unit of auxiliary flow of c1, or amount of auxiliary flow of c2 per unit of charging in c1.</td>
</tr>
<tr>
<td>PRC_ACTFLO (r,y,p,c)</td>
<td>Defines a conversion coefficient between the activity and the flow in commodity c. For storage processes, PRC_ACTFLO can be used for the commodities in the PCG in the standard way, but also for defining the amount of auxiliary flow of c per unit of activity.</td>
</tr>
<tr>
<td>NCAP_AFC (r,y,p,cg,tslvl)</td>
<td>Can be used for defining availability factors for the process activity (amount stored), process output flow, or process input flow, or any combination of these. See Section 6.3 for additional information.</td>
</tr>
<tr>
<td>NCAP_AFCS (r,y,p,cg,s)</td>
<td>As NCAP_AFC above, but can be specified for individual timeslices. NCAP_AFCS values override NCAP_AFC values defined at the same level.</td>
</tr>
</tbody>
</table>
4.3.7 Availability factors for storage processes

In TIMES, capacity by default bounds only the activity. For storage, this means the amount of stored energy. However, with the NCAP_AFC/NCAP_AFCS attributes, one can bound the output (or input) flows instead. Capacity then also refers to the nominal output (or input) capacity, e.g. electrical capacity of a pumped hydro power plant. In addition, one can bound simultaneously both the output and input flows by the capacity, which can be useful if the charging rate is limited by the capacity as well. Moreover, one can simultaneously define a bound also for the activity (the amount stored) in proportion to the same capacity variable. All these availability factors can be defined either on a desired timeslice level (NCAP_AFC), or on individual timeslices (NCAP_AFCS).

The rules for defining the availabilities for storage flows/activity can be summarized as follows:

- If the input/output commodities are different (c1/c2): Use NCAP_AFC(c1) for bounding the input flow and NCAP_AFC(c2) for bounding the output flow.
- If input=output=c, NCAP_AFC('NRG') will define the availability factor for both the input and output flow, while NCAP_AFC(c) will define the availability factor for the output flow only, overriding any NCAP_AFC('NRG') value if that is also specified (assuming NRG is the type of the stored commodity).
- NCAP_AFC('ACT') can additionally be used for bounding the activity (the amount stored); in this case one must bear in mind that any capacity expressed in power units (e.g. MW/GW) is assumed to represent a storage capacity equivalent to the amount produced by full power during one full year/week/day for SEASON/WEEKLY/DAYNITE level storage processes, respectively. Knowing this, the availability factor can be adjusted to correspond to the assumed real storage capacity. For example, a capacity of 1 GW is assumed to represent a storage capacity of 24 GWh for a DAYNITE storage, and if the real daily storage capacity is, say 8 GWh / GW, the maximum availability factor should be 0.333.

Remarks:
1. As any storage process has only a single capacity variable, the assumption is that the availabilities specified for the output/input flows and the activity are all proportional to the same capacity.
2. Note that any the availability factors defined by NCAP_AFC are multiplied by any NCAP_AF/NCAP_AFS/NCAT_AFA value if defined for the same timeslice.

4.3.8 Notes on other attributes for storage processes

There are important limitations of using standard processes parameters for storage processes. The most important limitations are summarized in Table 22, with regard to the parameters with the prefixes 'ACT_', 'FLO_' and 'PRC_'. In addition, none of the CHP parameters, IRE parameters (IRE_*), or dispatching parameters (ACT_MINLD, ACT_UPS, ACT_CSTUP, ACT_LOSPL, ACT_CSTPL, ACT_TIME), can be used for storage processes, and are ignored if used.
Table 22: Limitations of using standard process parameters for storage processes.

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Description</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACT_EFF</td>
<td>Activity efficiency</td>
<td>Can not be used</td>
</tr>
<tr>
<td>FLO_BND</td>

<td>Tax/subsidy for the production/use of commodity by process</td>
<td>Can only be used for auxiliary storage flows</td>
</tr>
<tr>
<td>PRC_MARK</td>
<td>Process group-wise market share bound</td>
<td>Same limitations as for FLO_MARK.</td>
</tr>
</tbody>
</table>

**Additional remark on peaking equations:**

- In peaking equations, storage processes producing the peaking commodity are by default taken into account by their capacity on the supply side, and not at all by their flows (charging/discharging). By defining the storage process as a member of the set PRC_PKNO, and also defining NCAP_PKCNT>0, the discharge from the storage is taken into account on the supply side instead of the capacity, and the charging into the storage is included on the consumption side (should such happen in the peak timeslice). That can be recommended, whenever the capacity represents the amount stored, and not the output capacity, and may be reasonable even for storage processes where the capacity represents the nominal maximum output flow.
5 Variables

This chapter describes each variable name, definition, and role in the TIMES Linear Program. To facilitate identification of the variables when examining the model’s source code, all variable names start with the prefix VAR_. The value assigned to each variable indexed by some time period, represents the average value in that time period, but the case of VAR_NCAP(v) is an exception, since that variable represents a point-wise investment decided at time period v. VAR_NCAP is discussed in detail below.

Table 23 is a list of TIMES variables by category, with brief description of each variable.

Remarks on Table 23:

- Many variables that are related to a process have two period indexes: \( t \) represents the current period, and \( v \) represents the vintage of a process, i.e. the period when the investment in that process was decided. For the VAR_NCAP variable, \( t \) is by definition equal to \( v \). For other variables, \( t \geq v \), if the process is vintaged \( \text{prc\_vint} \), i.e., the characteristics of the process depend on the vintage year. If the process is non-vintaged, the characteristics of the capacity of a process are not differentiated by its vintage structure, so that the vintage index is actually not needed for the variables of a non-vintaged process. In these cases, the vintage index \( v \) is by convention set equal to the period index \( t \).

- In Table 23, the variables are listed according to five categories, depending on what TIMES entity they represent. In the rest of the chapter, the variables are listed and fully described in alphabetical order.

- Table 23 does not list the variables used in the Climate Module, Damage Cost and ETL extensions of TIMES, which are fully documented in Appendices A, B, and C, respectively.

- In the Objective function category, Table 23 also lists several parameters that stand for certain portions of the objective functions. These are not bona fide GAMS variables, but mostly serve as convenient placeholders for this documentation, and also as useful parameters that may be reported in the solution.

#### User Constraint related

- **VAR_UC**: Variable representing the LHS expression of a user constraint summing over regions \((uc_r_sum)\), periods \((uc_t_sum)\) and timeslices \((uc_ts_sum)\).
- **VAR_UCR**: Variable representing the LHS expression of a user constraint summing over periods \((uc_t_sum)\) and timeslices \((uc_ts_sum)\) and being generated for the regions specified in \(uc_r_each\).
- **VAR_UCT**: Variable representing the LHS expression of a user constraint summing over regions \((uc_r_sum)\) and timeslices \((uc_ts_sum)\) and being generated for the periods specified in \(uc_t_each\).
- **VAR_UCRT**: Variable representing the LHS expression of a user constraint summing over timeslices \((uc_ts_sum)\) and being generated for the regions specified in \(uc_r_each\) and periods in \(uc_t_each\).
- **VAR_UCTS**: Variable representing the LHS expression of a user constraint summing over regions \((uc_r_sum)\) and being generated for the periods specified in \(uc_t_each\) and timeslices in \(uc_ts_each\).
- **VAR_UCRTS**: Variable representing the LHS expression of a user constraint summing over periods being generated for the regions specified in \(uc_r_each\), the periods in \(uc_t_each\) and timeslices in \(uc_ts_each\).

---

**Notation for indexes**: The following indexes are used in the remainder of this chapter:

- \(r, r' = \text{region; } v = \text{vintage; } t, t' = \text{time period; } y = \text{year; } p = \text{process; } c, c' = \text{commodity; } s, s' = \text{timeslice; } ie = \text{import or export; } l = \text{sense of a constraint (\(\geq, =, \text{or} \leq\)). In addition, some indexes (u; ble; opr; j; uc_n) are used for specific variables only and are defined in their context.}

#### 5.1 VAR_ACT\((r,v,t,p,s)\)

**Definition**: The overall activity of a process. VAR_ACT is defined by the EQ_ACTFLO equation either as the sum of outflows or as the sum of inflows of a particular (user selected) group of commodities, adequately normalized. If the process is not vintaged, the vintage index \(v\) is by convention set equal to the period index \(t\).

**Role**: Reports the activity of a process and implicitly defines how the capacity is measured, since the activity is bounded by the available capacity in the constraint

---

\(^{38}\) In case the dollar control parameter VAR_UC is set to YES, the user constraints are always strict equalities \((l=E)\) with the RHS constants replaced by the user constraint variables given in the table. The RHS bound parameter \((UC_RHS(R)(T)(S))\) are then applied to these user constraint related variables. See Section 5.20.
EQ(l)_CAPACT, e.g. if the activity of a coal power plant is defined over its electricity output, the capacity is measured in terms of the output commodity, e.g. MW_{electric}. Similarly, if the activity variable represents the input flow of coal, the capacity of the coal plant is measured in terms of the input commodity, e.g. MW_{coal}.

**Bounds:** Can be directly bounded by ACT_BND
**User constraints:** Can be directly referred to by UC_ACT

### 5.2 VAR_BLND(r,ble,opr)

**Definition:** amount of the blending stock opr in energy, volume or weight units needed for the production of the blending product ble in oil refinery modeling.

**Role:** used for specifying constraints on quality of the various refined petroleum products.

**Bounds:** Cannot be bounded.
**User constraints:** Cannot be referred to in user constraints.

### 5.3 VAR_CAP(r,t,p)

**Definition:** the installed capacity in place in any given year t, of all vintages of a process determined by the equation EQ(l)_CPT. The variable is equal to the sum of all previously made investments in new capacity, plus any remaining residual capacity installed before the modeling horizon, that has not yet reached the end of its technical lifetime, and minus any capacity that has been retired early.

**Role:** Its main purpose is to allow the total capacity of a process to be bounded. The variable is only created when
- capacity bounds (CAP_BND) for the total capacity installed are specified. In case only one lower or one upper capacity bound is specified, the variable is not generated, but the bound is directly used in the EQ(l)_CPT constraint.
- the capacity variable is needed in a user constraint, or
- the process is a learning technology (teg) in case that endogenous technological learning is used.

**Bounds:** Can be directly bounded by CAP_BND
**User constraints:** Can be directly referred to by UC_CAP

### 5.4 VAR_COMNET(r,t,c,s)

**Definition:** the net amount of a commodity at period t, timeslice s. It is equal to the difference between amount procured (produced plus imported) minus amount disposed (consumed plus exported).

**Role:** The variable is only created if a bound is imposed, or a cost is explicitly associated with the net level of a commodity.

**Bounds:** Can be directly bounded by COM_BNDNET
**User constraints:** Can be directly referred to by UC_COMNET
5.5 VAR_COMPRD(r,t,c,s)

**Definition:** the amount of commodity c procured at time period t, timeslice s.

**Role:** this variable is only created if a bound is imposed on total production of a commodity, or a cost is explicitly associated with production level of a commodity. The variable is defined through the equation EQE_COMPRD.

**Bounds:** Can be directly bounded by COM_BNDPRD

**User constraints:** Can be directly referred to by UC_COMPRD

5.6 VAR_CUMCOM(r,c,type,y1,y2)

**Definition:** the cumulative amount of commodity c produced in region r between years y1 and y2, over all timeslices. The type indicator (PRD/NET) distinguishes between gross and net production.

**Role:** this variable is only created if a bound is imposed on cumulative gross/net production of a commodity. The variable is defined through the equations EQ_CUMPRD and EQ_CUMNET.

**Bounds:** Can be directly bounded by COM_CUMNET/ COM_CUMPRD

**User constraints:** Can be directly referred to by UC_CUMCOM

5.7 VAR_CUMCST(r, y1,y2,costagg,cur)

**Definition:** the cumulative amount of costs/taxes/subsidies according to the aggregation costagg in region r between years y1 and y2, over all timeslices. The available cost aggregations are identified by the pre-defined members of the fixed index set costagg.

**Role:** this variable is only created if a bound is imposed on the cumulative amount of regional costs, taxes, and/or subsidies. The variable is defined through the equation EQ_BNDCST.

**Bounds:** Can be directly bounded by REG_CUMCST

**User constraints:** Cannot be referred to in user constraints

5.8 VAR_CUMFLO(r,p,c,y1,y2)

**Definition:** the cumulative amount of flow in commodity c by process p in region r between years y1 and y2, over all timeslices. With the commodity name c='ACT' (reserved system label), the variable represents the cumulative amount of process activity.

**Role:** this variable is only created if a bound is imposed on the cumulative amount of process flow or activity. The variable is defined through the equation EQ_CUMFLO.

**Bounds:** Can be directly bounded by FLO_CUM / ACT_CUM

**User constraints:** Can be directly referred to by UC_CUMFLO/UC_CUMACT
5.9 VAR_DNCAP(r,t,p,u) / VAR_SNCAP(r,t,p)

**Definition:** VAR_DNCAP is only used for processes selected by the user as being discrete, i.e. for which the new capacity in period t may only be equal to one of a set of discrete sizes, specified by the user. For such processes, VAR_DNCAP is a binary decision variable equal to 1 if the investment is equal to size ‘u’ and 0 otherwise. Thanks to an additional constraint, only one of the various potential sizes allowed for the investment at period t is indeed allowed.

VAR_SNCAP is only used for processes selected by the user as having semi-continuous amounts of new capacity, i.e. for which new capacity in period t may only be zero or between positive lower and upper bounds specified by the user.

**Role:** useful to mathematically express the fact that investment in process p at period t may only be done in discrete or semi-continuous sizes. See equation EQ_DSCNCAP in Chapter 6.

**Bounds:** Direct bounding not available, indirectly by NCAP_BND

**User constraints:** Not available

5.10 VAR_DRCAP(r,v,t,p,j)

**Definition:** this variable is used only for processes selected by the user as having discrete early capacity retirements, i.e. for which the retirement at period t may only be a multiple of a block size, specified by the user. For such processes, VAR_DRCAP is an integer decision variable equal to the number of blocks retired.

**Role:** needed for mathematically expressing the fact that early retirement in capacity of process p at period t may only be done in discrete amounts. See equation EQ_DSCRET in Chapter 6.

**Bounds:** Direct bounding not available, indirectly by RCAP_BND

**User constraints:** Not available

5.11 VAR_ELAST(r,t,c,s,j,l)

**Definition:** these variables are defined whenever a demand is declared to be price elastic. These variables are indexed by j, where j runs over the number of steps used for discretizing the demand curve of commodity c (c = energy service only). The jth variable stands for the portion of the demand that lies within discretization interval j, on side l (l indicates either increase or decrease of demand w.r.t. the reference case demand). Each ELAST variable is bounded upward via virtual equation EQ_BNDELAS.

**Role:** Each elastic demand is expressed as the sum of these variables. In the objective function, these variables are used to bear the cost of demand losses as explained in Part I, Chapter 4.

**Bounds:** Direct bounding not available, indirectly by COM_VOC/COM_STEP

**User constraints:** Not available
5.12 VAR_FLO(r,v,t,p,c,s)

**Definition:** these variables stand for the individual commodity flows in and out of a process. If the process is not vintaged, the vintage index v is by convention set equal to the period index t.

**Role:** The flow variables are the fundamental quantities defining the detailed operation of a process. They are used to define the activity of a process (VAR_ACT) in a user chosen manner. They are also essential for expressing various constraints that balance the flows of a commodity, or that control the flexibility of processes.

**Bounds:** Can be directly bounded by FLO_BND

**User constraints:** Can be directly referred to by UC_FLO

5.13 VAR_IRE(r,v,t,p,c,s,ie)

**Definition:** the inter-regional exchange variable (ie=Import, e=Export) that tracks import (ie=i) or export (ie=e) of a commodity between region r and other regions. The region(s) r' trading with r is (are) not specified via this variable, but rather via the process(es) p through which the import/export is accomplished. The topology set top_ire(r,c,r',c',p) of an exchange process indicates the (single) region r' with which region r is trading commodity c (which may have a different name c' in region r'). Each trade process may trade more than one commodity. Otherwise, VAR_IRE operates in a manner similar to VAR_FLO for conventional processes. An option exists for trading with an external region that is not modeled explicitly (exogenous trading). If the process is not vintaged, the vintage index v is by convention set equal to the period index t.

**Role:** the role of an IRE variable is to embody the amount of a commodity in or out of a trading process.

**Bounds:** Can be bounded by IRE_BND (directly for bilateral trade)

**User constraints:** Can be directly referred to by UC_IRE

5.14 VAR_NCAP(r,v,p)

**Definition:** the amount of new capacity (or what has traditionally been called “investment” in new capacity, or capacity build-up) at period v. As will be explained in Section 6.2.2, VAR_NCAP represents the total investment in technology p at period v only when ILED+TLIFE ≥ D(v), where D(v) is the period length. And, as discussed further in that Section, when ILED+TLIFE < D(v), the model assumes that the investment is repeated as many times as necessary within the period so that the life of the last repetition is beyond the end of period v. In this case VAR_NCAP represents the capacity level of the single investments. Figure 1 illustrates a case where the investment is made twice in period v (and some capacity still remains after period v). The average capacity in period v resulting from the investment VAR_NCAP(v) is less than VAR_NCAP(v), due to the delay ILED (it is equal to VAR_NCAP(v)* D(v)/TLIFE). The average capacity in period v+1 due to VAR_NCAP(v) is also less than VAR_NCAP(v) because the end of life of the second round of investment occurs before the end of period v+1. These adjustments are made in every equation involving VAR_NCAP by the internal parameter COEF_CPT.
**Figure 1: Example of a repeated investment in same period**

**Role:** The new capacity (i.e. investment) variables are fundamental in defining the investment decisions, and many other quantities derived from it (for instance process capacities). They play a key role in the model structure and intervene in the majority of constraints. They are notably used in equations that define the conservation of capacity and those that tie the activity of a process to its capacity. The omnipresence of VAR_NCAP is in part due to the fact that the VAR_CAP variable is not always defined in TIMES, by design. Note that residual capacity, or capacity in place prior to the initial model year, is handled as a constant in place of VAR_NCAP given by the input parameter NCAP_PASTI(y), which describes the investment made prior to the first period in the past year y.

**Bounds:** Can be directly bounded by NCAP_BND

**User constraints:** Can be directly referred to by UC_NCAP

### 5.15 VAR_OBJ(y₀) and related variables

**Definition:** equal to the objective function of the TIMES LP, i.e. the total cost of all regions, discounted to year y₀.

**Role:** this is the quantity that is minimized by the TIMES optimizer.

**Remark:** The next 10 ‘variables’ do not directly correspond to GAMS variables. They are used in the documentation (especially Section 6.2) as convenient intermediate placeholders that capture certain portions of the cost objective function. The reader is invited to look at Section 6.2 for detailed explanations on how these various costs enter the composition of the objective function. Most of these ‘variables’ are defined as reporting parameters that are made available to the VEDA-BE results analyser, as shown in Section 3.3.
5.15.1 **VAR_OBJR(r, y₀)**

**Definition:** equal to the sum of the various pieces of the total cost of region \( r \) discounted to year \( y₀ \).

**Role:** this is not a true variable in the GAMS code. It is used only as a convenient placeholder for writing the corresponding portion of the objective function in this documentation. It may also be reported in VEDA-BE.

5.15.2 **INVCOST(r,y)**

**Definition:** equal to the portion of the cost objective for year \( y \), region \( r \), that corresponds to investments.

**Role:** it is used mainly as a convenient placeholder for writing the corresponding portion of the objective function. It may also be reported in VEDA-BE.

5.15.3 **INVTAXSUB(r,y)**

**Definition:** equal to the portion of the cost objective for year \( y \), region \( r \), that corresponds to investment taxes and subsidies.

**Role:** it is used mainly as a convenient placeholder for writing the corresponding portion of the objective function. It may also be reported in VEDA-BE.

5.15.4 **INVDECOM(r,y)**

**Definition:** equal to the portion of the cost objective for year \( y \), region \( r \), that corresponds to capital costs linked to decommissioning of a process.

**Role:** it is used mainly as a convenient placeholder for writing the corresponding portion of the objective function. It may also be reported in VEDA-BE.

5.15.5 **FIXCOST(r,y)**

**Definition:** equal to the portion of the cost objective for year \( y \), region \( r \), that corresponds to fixed annual costs.

**Role:** it is used mainly as a convenient placeholder for writing the corresponding portion of the objective function. It may also be reported in VEDA-BE.

5.15.6 **FIXTAXSUB(r,y)**

**Definition:** equal to the portion of the cost objective for year \( y \), region \( r \), that corresponds to taxes and subsidies attached to fixed annual costs.

**Role:** it is used mainly as a convenient placeholder for writing the corresponding portion of the objective function. It may also be reported in VEDA-BE.

5.15.7 **VARCOST(r,y)**

**Definition:** equal to the portion of the cost objective for year \( y \), region \( r \), that corresponds to variable annual costs.

**Role:** it is used mainly as a convenient placeholder for writing the corresponding portion of the objective function. It may also be reported in VEDA-BE.

5.15.8 **VARTAXSUB(r,y)**

**Definition:** equal to the portion of the cost objective for year \( y \), region \( r \), that corresponds to variable annual taxes and subsidies.

**Role:** it is used mainly as a convenient placeholder for writing the corresponding portion of the objective function. It may also be reported in VEDA-BE.
5.15.9 ELASTCOST(r,y)

**Definition:** equal to the portion of the cost objective for year y, region r, that corresponds to the cost incurred when demands are reduced due to their price elasticity.

**Role:** it is used mainly as a convenient placeholder for writing the corresponding portion of the objective function. It may also be reported in VEDA-BE.

5.15.10 LATEREVENUES(r,y)

**Definition:** equal to the portion of the cost objective for year y, region r, that corresponds to certain late revenues from the recycling of materials from dismantled processes that occur after the end-of-horizon.

**Role:** this is not a true variable in the GAMS code. It is used only as a convenient placeholder for writing the corresponding portion of the objective function in this documentation. It may also be reported in VEDA-BE as a convenient replacement for the sum of the components of the total cost.

5.15.11 SALVAGE(r,y0)

**Definition:** equal to the portion of the cost objective for region r, that corresponds to the salvage value of investments and other one-time costs. It is discounted to some base year y0.

**Role:** it is used mainly as a convenient placeholder for writing the corresponding portion of the objective function. It may also be reported in VEDA-BE.

5.16 VAR_RCAP(r,v,t,p)

**Definition:** this variable is used only for processes selected by the user as having early capacity retirements. For such processes, VAR_RCAP represents the amount of capacity of vintage v retired in period t.

**Role:** introduced for supporting bounds on the amount of retired capacity of process p and vintage v in period t.

**Bounds:** Can be directly bounded by RCAP_BND

**User constraints:** Not available

5.17 VAR_SCAP(r,v,t,p)

**Definition:** this variable is used only for processes selected by the user as having early capacity retirements. For such processes, VAR_SCAP represents the cumulative amount of capacity of vintage v retired in periods tt ≤ t.

**Role:** needed in several TIMES equations for adjusting the overall available capacity of process p at period t according to the amount of capacity already retired.

**Bounds:** Not directly available; indirectly by RCAP_BND / CAP_BND

**User constraints:** Not available
5.18 VAR_SIN/SOUT(r,v,t,p,c,s)

**Definition:** flow entering/leaving at period t a storage process p, storing commodity c. The process may be vintaged. If the process is not vintaged, the vintage index v is by convention set equal to the period index t. For storages between timeslices (prc_stgtss) and night-storage devices (prc_nsttss) the timeslice index s of the storage flows is determined by the timeslice resolution of the storage (e.g. DAYNITE for a day storage). For a storage operating between periods (prc_stgips), the storage flows are always on an annual level and hence the timeslice s is then always set to ANNUAL.

**Role:** to store some commodity so that it may be used in a time slice or period different from the one in which it was procured; enters the expressions for the storage constraints.

**Bounds:** Can be directly bounded by STGIN_BND/STGOUT_BND

**User constraints:** Not directly available; indirectly by using auxiliary storage flows

5.19 VAR_UPS(r,v,t,p,s,l)

**Definition:** amount of off-line capacity (l='N'), started-up capacity (l='UP'), shut-down capacity (l='LO'), or efficiency losses due to partial loads (l='FX') in period t process p vintage index v.

**Role:** used for modeling capacity dispatching, start-up costs as well as partial load efficiencies, but only when requested so by the user.

**Bounds:** Not available

**User constraints:** Not directly available; in timeslice-dynamic constraints on-line capacity can be referred by UC_CAP, using the ONLINE modifier for CAP

5.20 Variables used in User Constraints

The remaining TIMES variables are all attached to user constraints. User constraints are quite flexible, and may involve any of the usual TIMES variables. Two variants of formulating user constraints exist. In the first case a LHS expression, containing expressions involving the different TIMES variables, are bounded by a RHS constant (given by the input parameter UC_RHS(R)(T)(S)). In the second case, the constant on the RHS is replaced by a variable. The bound UC_RHS(R)(T)(S) is then applied to this variable. In the latter case, the user constraints are always generated as strict equalities, while in the first case the equation sign of the user constraint is determined by the bound type.

- Case 1 (RHS constants): \(<\text{LHS expression}> \leq/\geq \text{UC_RHS(R)(T)(S)}\)
- Case 2 (UC variables): \(<\text{LHS expression}> = \text{VAR_UC(R)(T)(S)}\)

These user constraint variables are in fact redundant, but quite useful in providing streamlined expressions constraints (see Chapter 6), and allow for reporting the slack level of each UC. Moreover, in the case of range constraints, they will reduce model size and the amount of input data. By setting the dollar control parameter VAR_UC to YES in the run-file, the variable based formulation is activated (second case). By default, the formulation without user constraint variables will be used, and only the marginals of the equations are reported.
Non-binding user constraints (introduced for reporting purposes) can only be defined when the user constraint variables are used (i.e. \texttt{VAR\_UC == YES}). Each of the listed variables is related to a specific class of user constraint depending on whether the user constraint is created for each period, region, or time slice or only a subset of these indices. In addition, some user constraints are defined for pair of successive time periods (dynamic user constraint or growth constraint). Each variable has at least one index (representing the user constraint \texttt{uc\_n} for which this variable is defined), and may have up to three additional indexes among \texttt{r}, \texttt{t}, and \texttt{s}.

5.20.1 \texttt{VAR\_UC(uc\_n)}

Variable representing the LHS expression of the user constraint \texttt{EQE\_UC(uc\_n)} summing over regions (\texttt{uc\_r\_sum}), periods (\texttt{uc\_t\_sum}) and timeslices (\texttt{uc\_ts\_sum}).

5.20.2 \texttt{VAR\_UCR(uc\_n,r)}

Variable representing the LHS expression of the user constraint \texttt{EQE\_UCR(r,uc\_n)} summing over periods (\texttt{uc\_t\_sum}) and timeslices (\texttt{uc\_ts\_sum}) and being generated for the regions specified in \texttt{uc\_r\_each}.

5.20.3 \texttt{VAR\_UCT(uc\_n,t)}

Variable representing the LHS expression of the user constraint \texttt{EQE\_UCT(uc\_n,t)} and the combined LHS–RHS expression of the user constraint \texttt{EQE\_UCSU(uc\_n,t)}, summing over regions (\texttt{uc\_r\_sum}) and timeslices (\texttt{uc\_ts\_sum}) and being generated for the periods specified in \texttt{uc\_t\_each/uc\_t\_succ}.

5.20.4 \texttt{VAR\_UCRT(uc\_n,r,t)}

Variable representing the LHS expression of the user constraint \texttt{EQE\_UCRT(r,uc\_n,t)} and the combined LHS–RHS expression of the user constraint \texttt{EQE\_UCRSU(r,uc\_n,t)}, summing over timeslices (\texttt{uc\_ts\_sum}) and being generated for the regions specified in \texttt{uc\_r\_each} and periods in \texttt{uc\_t\_each/uc\_t\_succ}.

5.20.5 \texttt{VAR\_UCTS(uc\_n,t,s)}

Variable representing the LHS expression of the user constraint \texttt{EQE\_UCTS(uc\_n,t,s)} and the combined LHS–RHS expression of the user constraint \texttt{EQE\_UCSUS(uc\_n,t,s)}, summing over regions (\texttt{uc\_r\_sum}) and being generated for the periods specified in \texttt{uc\_t\_each/uc\_t\_succ} and timeslices in \texttt{uc\_ts\_each}.

5.20.6 \texttt{VAR\_UCRTS(uc\_n,r,t,s)}

Variable representing the LHS expression of the user constraint \texttt{EQE\_UCRTS(r,uc\_n,t,s)} and the combined LHS–RHS expression of the user constraint \texttt{EQE\_UCRSUS(r,uc\_n,t,s)}, being generated for the regions specified in \texttt{uc\_r\_each}, the periods in \texttt{uc\_t\_each/uc\_t\_succ} and the timeslices in \texttt{uc\_ts\_each}.
6 Equations

This chapter is divided into four sections: the first section describes the main notational conventions adopted in writing the mathematical expressions of the entire chapter. The next two sections treat respectively the TIMES objective function and the standard linear constraints of the model. The fourth section is devoted to the facility for defining various kinds of user constraints. Additional constraints and objective function additions that are required for the Climate Module, Damage Cost and Endogenous Technology Learning options are described in Appendices A, B and C, respectively.

Each equation has a unique name and is described in a separate subsection. The equations are listed in alphabetical order in each section. Each subsection contains successively the name, list of indices, and type of the equation, the related variables and other equations, the purpose of the equation, any particular remarks applying to it, and finally the mathematical expression of the constraint or objective function.

The mathematical formulation of an equation starts with the name of the equation in the format: $\text{EQ}_{XXX_{ijkl}}$, where $XXX$ is a unique equation identifier, and $i,j,k,...$, are the equation indexes, among those described in chapter 2. Some equation names also include an index $l$ controlling the sense of the equation. Next to the equation name is a logical condition that the equation indexes must satisfy. That condition constitutes the domain of definition of the equation. It is useful to remember that the equation is created in multiple instances, one for each combination of the equation indexes that satisfies the logical condition, and that each index in the equation’s index list remains fixed in the expressions constituting each instance of the equation.

6.1 Notational conventions

We use the following mathematical symbols for the mathematical expressions and relations constituting the equations:

The conditions that apply to each equation are mathematically expressed using the $\in$ symbol (meaning “such that” or “only when”), followed by a logical expression involving the usual logic operators: $\land$ (AND), $\lor$ (OR), and NOT.

Within the mathematical expressions of the constraints, we use the usual symbols for the arithmetic operators ($+, -, \times, /, \Sigma$, etc).

However, in order to improve the writing and legibility of all expressions, we use some simplifications of the usual mathematical notation concerning the use of multiple indexes, which we describe in the next two subsections.

6.1.1 Notation for summations

When an expression $A(i,j,k,...)$ is summed, the summation must specify the range over which the indexes are allowed to run. Our notational conventions are as follows:

When a single index $j$ runs over a one-dimensional set $A$, the usual notation is used, as in: $\sum_{j \in A} Expression_j$, where $A$ is a single dimensional set.
When a summation must be done over a subset of a multi-dimensional set, we use a simplified notation where some of the running indexes are omitted, if they are not active for this summation.

**Example:** consider the 3-dimensional set \( \text{top} \) consisting of all quadruples \( \{r,p,c,io\} \) such that process \( p \) in region \( r \), has a flow of commodity \( c \) with orientation \( io \) (see table 3 of chapter 2). If it is desired to sum an expression \( A_{r,p,c,io} \) over all commodities \( c \), keeping the region (\( r \)), process (\( p \)) and orientation (\( io \)) fixed respectively at \( r_1 \), \( p_1 \) and ‘IN’, we will write, by a slight abuse of notation:

\[
\sum_{c \in \text{top}} A(r_1, p_1, c, 'IN')
\]

, or even more simply:

\[
\sum_{c \in \text{top}} A(r_1, p_1, c, 'IN')
\]

, if the context is unambiguous. Either of these notations clearly indicates that \( r, p \) and \( io \) are fixed and that the only active running index is \( c \).

(The traditional mathematical notation would have been:

\[
\sum_{\{r_1,p_1,c,IN\} \in \text{top}} A(r_1, p_1, c, 'IN')
\]

but this may have hidden the fact that \( c \) is the only running index active in the sum).

### 6.1.2 Notation for logical conditions

We use similar simplifying notation in writing the logical conditions of each equation. A logical condition usually expresses that some parameter exists (i.e. has been given a value by the user), and/or that some indexes are restricted to certain subsets.

A typical example of the former would be written as: \( \exists \text{ACTBD}_{r,t,p,s,bd} \), which reads: “the user has defined an activity bound for process \( p \) in region \( r \), time-period \( t \), timeslice \( s \) and sense \( bd \)”. The indexes may sometimes be omitted, when they are the same as those attached to the equation name.

A typical example of the latter is the first condition for equation \( \text{EQ_ACTFLO}_{r,v,t,p,s} \) (see section 6.3.4), which we write simply as: \( \text{rtp_vintyr} \), which is short for: \( \{r,v,t,p\} \in \text{rtp_vintyr} \), with the meaning that “some capacity of process \( p \) in region \( r \), created at period \( v \), exists at period \( t \)”. Again here, the indices have been omitted from the notation since they are already listed as indices of the equation name.

### 6.1.3 Using Indicator functions in arithmetic expressions

There are situations where an expression \( A \) is either equal to \( B \) or to \( C \), depending on whether a certain condition holds or not, i.e.:

\[
A = B \text{ if } Cond
\]

\[
A = C \text{ if } \neg Cond
\]

This may also be written as:

\[
A = B \times \text{Cond} + C \times \neg \text{Cond}
\]

where it is understood that the notation (\( \text{Cond} \)) is the indicator function of the logical condition, i.e. (\( \text{Cond} \)=1 if Cond holds, and 0 if not.)
This notation often makes equations more legible and compact. A good example appears in EQ_CAPACT.

6.2 Objective function EQ_OBJ

Equation EQ_OBJ
Indices: region (r); state of the world (w); process (p); time-slice (s); and perhaps others ...
Type: = Non Binding (MIN)

Related Variables: All

Purpose: the objective function is the criterion that is minimized by the TIMES model. It represents the total discounted cost of the entire, possibly multi-regional system over the selected planning horizon. It is also equal to the negative of the discounted total surplus (plus a constant), as discussed in PART I, chapters 3 and 4.

6.2.1 Introduction and notation

The TIMES objective function includes a number of innovations compared to those of more traditional energy models such as MARKAL, EFOM, MESSAGE, etc. The main design choices are as follows:

- The objective function may be thought of as the discounted sum of *net annual costs* (i.e. costs minus revenues), as opposed to *net period costs*. Note that some costs and revenues are incurred after the end of horizon (EOH). This is the case for instance for some investment payments and more frequently for payments and revenues attached to decommissioning activities. The past investments (made before the first year of the horizon) may also have payments within horizon years (and even after EOH!) These are also reflected in the objective function. However, it should be clear that such payments are shown in OBJ only for reporting purposes, since such payments are entirely *sunk*, i.e. they are not affected by the model’s decisions.

- The model uses a general discount rate \( d(y) \) (year dependent), as well as technology specific discount rates \( d_s(t) \) (period dependent). The former is used to: a) discount fixed and variable operating costs, and b) discount investment cost payments from the point of time when the investment actually occurs to the base year chosen for the computation of the present value of the total system cost. The latter are used only to calculate the annual payments resulting from a lump-sum

---

39 The actual implementation of OBJ in the GAMS program is different from the one described in the documentation, since the annualizing of the various cost components is not performed in the GAMS code of the OBJ equation, but rather in the reporting section of the program, for improved code performance. However, despite the simplification, the GAMS code results in an objective function that is fully equivalent to the one in this documentation.
investment in some year. Thus, the only place where \( d_s(t) \) intervenes is to compute the Capital Recovery Factors (CRF) discussed further down.

For convenience, we summarize below the notation which is more especially used in the objective function formulation (see Section 6.1 for general notes on the notation).

6.2.1.1 Notation relative to time

**MILESTONEYEARS**: the set of all milestone years (by convention: middle years, see below \( M(t) \))

**PASTYEARS**: Set of years prior to start of horizon, for which there is a past investment (after interpolation of user data).

**MODELYEARS**: any year within the model’s horizon

**FUTUREYEARS**: set of years posterior to EOH

**YEARS** set of years before during and after planning horizon

\( t \) any member of **MILESTONEYEARS** or **PASTYEARS**. By convention, a period \( t \) is represented by its middle year (see below \( M(t) \)). This convention can be changed without altering the expressions in this document.

\( B(t) \) : the first year of the period represented by \( t \)

\( E(t) \) : the last year of the period represented by \( t \)

\( D(t) \) : the number of years in period \( t \). By default, \( D(t)=1 \) for all past years. Thus, \( D(t)=E(t)−B(t)+1 \)

\( M(t) \) : the “middle” year or milestone year of period \( t \). Since period \( n \) may have an even or an odd number of years, \( M(t) \) is not always exactly centered at the middle of the period. It is defined as follows: \( M(t) = \lfloor B(t)+D(t)−1)/2 \rfloor \), where \( \lfloor x \rfloor \) indicates the largest integer less than or equal to \( x \). For example, period from 2011 to 2020 includes 10 years, and its “middle year” is \([2011+4.5]\) or 2015 (slightly left of the middle), whereas the period from 2001 to 2015 has 15 years, and its “middle year” is : \([2001+7]\) or 2008 (i.e. the true middle in this example)

\( y \) : running year, ranging over **MODELYEARS**, from \( B_0 \) to \( EOH \).

\( k \) : dummy running index of any year, even outside horizon

\( v \) : running index for a year, used when it represents a vintage year for some investment.

\( v(p) \) : vintage of process \( p \) (defined only if \( p \) is vintaged)

\( B_0 \) : initial year (the single year of first period of the model run)

**EOH** : Last year in horizon for a given model run.

Similarly, by a slight abuse of notation, the above entities are extended as follows, when the argument is a particular year, rather than a model year:

\( B(y) \) : first year of the period containing year \( y \) (instead of \( B(T(y)) \))

\( T(y) \) : the milestone year of the period containing year \( y \) (same as \( M(y) \) in our present convention)

\( M(y) \) : “middle year” of the period containing year \( y \) (instead of \( M(T(y)) \))

\( D(y) \) : number of years of the period containing year \( y \) (instead of \( D(T(y)) \))
6.2.1.2 Other notation

\(d(y)\) : general (social) discount rate (time dependent, although not shown in notation)

\(r(y)\) : general discount factor: \(r(y) = 1/(1+d(y))\) (time dependent, although not shown in notation)

\(d_s(t)\) : technology specific discount rate (model year dependent)

\(r_s(t)\) : technology specific discount factor: \(r_s(t) = 1/(1+d_s(t))\)

\(DISC(y,z)\) : Value, discounted to the beginning of year \(z\), of a $1 payment made at beginning of year \(y\), using general discount factor. \(DISC(y,z) = \prod_{u=z}^{y-1} r(u)\)

\(CRF_s(t)\) : Capital recovery factor, using a (technology specific) discount rate and an economic life appropriate to the payment being considered. This quantity is used to replace an investment cost by a series of annual payments spread over some span of time \(CRF_s = (1-r_s(t))/(1-r_s(t)^{ELIFE})\). Note that a \(CRF\) using the general discount rate is also defined and used in the \(SALVAGE\) portion of the objective function.

\(OBJ(z)\) : Total system cost, discounted to the beginning of year \(z\)

\(INDIC(x)\) : 1 if logical expression \(x\) is true, 0 if not

\(\langle E \rangle\) is the smallest integer larger than or equal to \(E\)

6.2.1.3 Reminder of some technology attribute names (each indexed by \(t\))

\(TLIFE\) : Technical life of a technology

\(ELIFE\) : Economic life of a technology, i.e. period over which investment payments are spread (default = \(TLIFE\))

\(DLAGE\) : Lag after end of technical life, after which decommissioning may start

\(DLIFE\) : Duration of decommissioning for processes with \(ILED > 0\), (otherwise =1)

\(DELIF\) : Economic life for decommissioning purposes (default \(DLIFE\)).

\(ILED\) : Lead-time for the construction of a process. \(TLIFE\) starts after the end of \(ILED\)

\(ILED_{Min} = \min\{1/10 \times D(t), 1/10 \times TLIFE\}\) This threshold serves to distinguish small from large projects; it triggers a different treatment of investment timing.

6.2.1.4 Discounting options

There are alternate discounting methods in TIMES. The default method is to assume that all payments occur at the beginning of some year. Alternate methods (activated by a switch, see PART III) assume that investments are incurred at the beginning of some year, but that all annual (or annualized) payments occur at the middle or at the end of the corresponding year. Section 0 explains the different methods.

\(^{40}\) This is the default definition adopted for \(CRF\), corresponding to beginning-of-year discounting. For other discounting options, see Section 0.
6.2.1.5 Components of the Objective function

The objective function is the sum of all regional objectives, all of them discounted to the same user-selected base year, as shown in equation (A) below.

\[ EQ\_OBJ(z) \quad \exists \ z \in ALLYEARS \]

\[ VAR\_OBJ(z) = \sum_{r \in REG} REG\_OBJ(z, r) \]  

(A)

Each regional objective \( OBJ(z, r) \) is decomposed into the sum of nine components, to facilitate exposition, as per expression (B) below.

\[ EQ\_OBJ(z, r) \quad \exists \ z \in ALLYEARS, \ r \in REG \]

\[ REG\_OBJ(z, r) = \sum_{y \in (-\infty, \infty)} DISC(y, z) \times \left\{ \begin{array}{l}
INVCOST(y) + INV\_TAX\_SUB(y) + INV\_DECOM(y) +\\
FIX\_COST(y) + FIX\_TAX\_SUB(y) + SURV\_COST(y) +\\
VAR\_COST(y) + VARTAX\_SUB(y) + ELAST\_COST(y) -\\
LAT\_REVENUES(y) - SALV\_AGE(z)
\end{array} \right\} \]  

(B)

The regional index \( r \) is omitted from the nine components for simplicity of notation.

The first and second terms are linked to investment costs. The third term is linked to decommissioning capital costs, the fourth and fifth terms to fixed annual costs, the seventh and eighth terms to all variable costs (costs proportional to some activity), and the ninth to demand loss costs. The tenth cost (actually a revenue) accounts for commodity recycling occurring after \( EOH \), and the eleventh term is the salvage value of all capital costs of technologies whose life extends beyond \( EOH \). The 11 components are presented in the nine subsections 6.2.2 to 6.2.10.

6.2.2 Investment costs: INVCOST(y)

This subsection presents the components of the objective function related to investment costs, which occur in the year an investment is decided and/or during the construction lead-time of a facility.

Remarks

a) The investment cost specified by using the input attribute NCAP\_COST should be the overnight investment cost (excluding any interests paid during construction) whenever the construction lead time is explicitly modeled (i.e. cases 2 are used, see below). In such a case, the interests during construction are endogenously calculated by the model itself, as will be apparent in the sequel. If no lead-time is specified (and
thus cases 1 are used), the full cost of investments should be used (including interests during construction, if any).\footnote{41}

b) Each individual investment physically occurring in year \( k \), results in a \textit{stream of annual payments} spread over several years in the future. The stream starts in year \( k \) and covers years \( k, k+1, \ldots, k+\text{ELIFE}-1 \), where \( \text{ELIFE} \) is the economic life of the technology. Each yearly payment is equal to a fraction \( CRF \) of the investment cost \((CRF = \text{Capital Recovery Factor})\). Note that if the technology discount rate is equal to the general discount rate, then the stream of \( \text{ELIFE} \) yearly payments is equivalent to a single payment of the whole investment cost located at year \( k \), inasmuch as both have the same discounted present value. If however the technology’s discount rate is chosen different from the general one, then the stream of payments has a different present value than the lump sum at year \( k \). It is the user’s responsibility to choose technology dependent discount rates, and therefore to decide to alter the effective value of investment costs.

c) In addition to spreading the payments resulting from investment costs, a major TIMES refinement is that the physical investment itself does not occur in a single year, but rather as a series of annual increments. For instance, if the model invests 3 GW of electric capacity in a period extending from 2011 to 2020, the physical capacity increase may be delayed and/or may be spread over several years. The exact way the delaying and spreading are effected depends on several conditions, which are specified further down as four separate cases, and which are functions both of the nature of the technology and of the length of the period in which the investment takes place relative to the technology’s technical life. The spreading of investments and the spreading of payments described in the previous paragraph help guarantee a smooth trajectory for most investment payments, a more realistic representation than what happens in other models. The Case 1.a example given below shows a case where the physical investment is spread over four years, and each increment’s capital payments are further spread over 3 years.

d) The above two remarks entail that payments of investment costs may well extend beyond the horizon. We shall also see that some investment payments occur in years prior to the beginning of the planning horizon (cases 1 only).

e) Taxes and subsidies on investments are treated exactly as investment costs in the objective function.

f) Since the model has the capability to represent \textit{sunk} materials and energy carriers (i.e. those embedded in a technology at construction time, such as the uranium core of a nuclear reactor, or the steel imbedded in a car), these sunk commodities have an impact on cost. Two possibilities exist: if the material is one whose production is explicitly modeled in the RES, then there is no need to indicate the cost corresponding to the sunk material, which will be implicitly accounted for by the model just like any other flow. If on the other hand the material is not specifically modeled in the RES, then the cost of the sunk material should be included in the technology’s investment cost, and will then be handled exactly as investment costs.

\footnote{41}{Ideally, it would be desirable that cases 1 be used only for those investments that have no lead time (and thus no interest during construction). However, if cases 1 are employed even for projects with significant IDC’s, these should have their IDC included in the investment cost.}
The four investment cases

As mentioned above, the timing of the various types of payments and revenues is made as realistic and as smooth as possible. All investment decisions result in increments and/or decrements in the capacity of a process, at various times. These increments or decrements may occur, in some cases, in one large lump, for instance in the case of a large project (hydroelectric plant, aluminum plant, etc.), and, in other cases, in small additions or subtractions to capacity (e.g. buying or retiring cars, or heating devices). Depending on which case is considered, the assumption regarding the corresponding streams of payments (or revenues) differs markedly. Therefore, the distinction between small and large projects (called cases 1 and 2 below) will be crucial for writing the capital cost components of the objective function. A second distinction comes from the relative length of a project’s technical life vs. that of the period when the investment occurs. Namely, if the life of an investment is less than the length of the period, then it is clear that the investment must be repeated all along the period. This is not so when the technical life extends beyond the period’s end. Altogether, these two distinctions result in four mutually exclusive cases, each of which is treated separately. In what follows, we present the mathematical expression for the INVCOST component and one graphical example for each case.

Case 1.a If \( ILED_t \leq ILED_{Min,t} \) and \( TLIFE_t + ILED_t \geq D(t) \)

(Small divisible projects, non-repetitive, progressive investment in period)

Here, we make what appears to be the most natural assumption, i.e. that the investment occurs in small yearly increments spread linearly over \( D(t) \) years. Precisely, the capacity additions start at year \( M(t)-D(t)+1 \), and end at year \( M(t) \), which means that payments start earlier than the beginning of the period, and end at the middle of the period, see example. This seems a more realistic compromise than starting the payments at the beginning of the period and stopping them at the end, since that would mean that during the whole period, the paid for capacity would actually not be sufficient to cover the capacity selected by the model for that period.
**EQ_INVCOST(y)**

\[ \text{INVCOSt}(y) = \sum_{t=MILESTONE:PASTYS} INDIC(1.a) \times \sum_{v=\max(M(t)-D(t)+1,y-ELIFE_t-1)}^{\min(M(t),y)} \left( \frac{\text{VAR_NCAP}_t}{D(t)} + \text{NCAP_PASTI}_t \right) \times \text{CRF}_v \times \text{NCAP_COST}_v \]

*Useful Range for y:*

\( \{M(t) - D(t) + 1, M(t) + ELIFE_t - 1\} \)

**Comments:** The summand represents the payment effected in year \( y \), due to the investment increment that occurred in year \( v \) (recall that investment payments are spread over \( ELIFE \)). The summand consists of three factors: the first is the amount of investment in year \( v \), the second is the capital recovery factor, and the third is the unit investment cost.

The outer summation is over all periods (note that periods later than \( T(y) \) are relevant, because when \( y \) falls near the end of a period, the next period’s investment may have already started). The inner summation is over a span of \( D(t) \) centered at \( B(t) \), but truncated at year \( y \). Also, the lower summation bound ensures that an investment increment which occurred in year \( v \) has a payment in year \( y \) only if \( y \) and \( v \) are less than \( ELIFE \) years apart.
Case 1.b if $ILED_i \leq ILED_{\text{Min},t}$ and $TLIFE_i + ILED < D(t)$

Small projects, repeated investments in period

Note that in this case the investment is repeated as many times as necessary to cover the period length (see figure). In this case, the assumption that the investment is spread over $D(t)$ years is not realistic. It is much more natural to spread the investment over the technical life of the process being invested in, because this ensures a smooth, constant stream of small investments during the whole period (any other choice of the time span over which investment is spread, would lead to an uneven stream of incremental investments). The number of re-investments in the period is called $C$, and is easily computed so as to cover the entire period. As a result of this discussion, the first investment cycle starts at year $\left\lfloor B(t) - TLIFE_i / 2 \right\rfloor$ (meaning the smallest integer not less than the operand), and ends $TLIFE$ years later, when the second cycle starts, etc, as many times as necessary to cover the entire period. The last cycle extends over the next period(s), and that is taken into account in the capacity transfer equations of the model. As before, each capacity increment results in a stream of $ELIFE$ payments at years $v$, $v+1$, etc.

\[
\text{INVCOST}(y) = \sum_{t \in \text{MILESTONE}} \text{INDIC(1,b)} \times \sum_{v = \text{Max}(\{B(t) - TLIFE_i / 2\}, y - ELIFE_i + 1)}^{\text{Min}(\{B(t) - TLIFE_i / 2\} + C \times TLIFE_i, y - 1)} \frac{\text{VAR} - NCAP_t}{\text{TLIFE}_t} \times CRF_t \times NCAP \_COST_v
\]

Relevant range for $y$:

\[
\left\lfloor B(t) - TLIFE_i / 2 \right\rfloor, \left\lfloor B(t) - TLIFE_i / 2 \right\rfloor + C \times TLIFE_i + ELIFE_i - 2
\]

(I.1.b)
Comments: the expression is similar to that in case 1.a, except that i) the investment is spread over the technical life rather than the period length, and ii) the investment cycle is repeated more than once.

Case 2.a: $ILED_t > ILED_{Min,t}$ and $ILED_t + TLIFE_t \geq D(t)$

(Large, indivisible projects, unrepeated investment in period)

Here, it is assumed that construction is spread over the lead-time (a very realistic assumption for large projects), and capacity becomes available at the end of the lead time, in a lump quantity (see figure).

\[
INV_{COST}(y) = \sum_{t \in \text{MILESTONE YEARS}} INDIC(2.a) \times \sum_{k = \max\{B(t), y-ELIFE_t, 1\}}^{\min\{B(t)+ILED_t, -1, y\}} \left( \frac{\text{VAR}_t \text{NCAP}_t}{ILED_t} \right) \times CRF_t \times NCAP_\text{COST}_t \times B(t)+ILED_t \\
+ \sum_{t \in \text{PAST YEARS}} INDIC(2.a) \times \sum_{k = \max\{t-ILED_t, y-ELIFE_t, 1\}}^{\min\{t+ILED_t, -1, y\}} \left( \frac{\text{NCAP}_t \text{PASTI}_t}{ILED_t} \right) \times CRF_t \times NCAP_\text{COST}_t
\]

Useful Range for $y$:
\[
\{B(t), B(t) + ILED_t + ELIFE_t, 2\}
\]

(1.2.a)
Comment: the main difference with case I.1.a) is that the investment’s construction starts at year $B(t)$ and ends at year $B(t) + ILED_t - 1$ (see example). As before, payments for each year’s construction spread over $ELIFE$ years.

**Case 2.b:** $ILED > ILED_{Min,t}$ and $TLIFE_t + ILED_t < D(t)$

(Large, indivisible Projects, repeated investments in period)

This case is similar to case I.2.a, but the investment is repeated more than once over the period, each cycle being $TLIFE$ years long. As in case I.2.a, each construction is spread over one lead time, $ILED$. In this case, the exact pattern of yearly investments is complex, so that we have to use an algorithm instead of a closed form summation.

**ALGORITHM** (Output: the vector of payments $P_t(y)$ at each year $y$, due to VAR_NCAP)

**Step 0:** Initialization ($NI(t)$ represents the amount of new investment made in year $u$)

$NI_t(u) := 0 \quad \forall B(t) \leq u \leq B(t) + ILED_t + (C-1) \times TLIFE_t - 1$

**Step 1:** Compute number of repetitions of investment

$$C = \left\lfloor \frac{D(t) - ILED_t}{TLIFE_t} \right\rfloor$$
**Step 2:** for each year $u$ in range:

$$B(t) \leq u \leq B(t) + ILED_i + (C - 1) \cdot TLIFE_i - 1$$

Compute:

For $I = 1$ to $C$

For $u = B(t) + (I - 1) \cdot TLIFE_i$ to $B(t) + (I - 1) \cdot TLIFE_i + ILED_i - 1$

$$NI_i(u) := NI_i(u) + \frac{NCAP\_COST_{B(t)+(I-1)\cdot TLIFE_i + ILED_i}}{ILED_i}$$

Next $u$

Next $I$

**Step 3:** Compute payments incurred in year $y$, and resulting from variable $VAR\_NCAP_i$

For each $y$ in range:

$$B(t) \leq y \leq B(t) + (C - 1) \cdot TLIFE_i + ILED_i + ELIFE_i - 2$$

Compute:

$$P_i(y) = \sum_{u=\text{Max}\{B(t),y-ELIFE_i+1\}}^{y} NI_i(u) \times VAR\_NCAP_i \times CRF_s$$

**END ALGORITHM**

$$INVCOST(y) = \sum_{t=MILESTONES, t \leq T(y)} INDIC(2.b) \times P_i(y)$$

### 6.2.3 Taxes and subsidies on investments

We assume that taxes/subsidies on investments occur at precisely the same time as the investment. Therefore, the expressions $INVTAXSUB(y)$ for taxes/subsidies are identical to those for investment costs, with $NCAP\_COST$ replaced by: $(NCAP\_ITAX - NCAP\_ISUB)$. 
6.2.4 Decommissioning (dismantling) capital costs: \textit{INVDECOM}(y)

**Remarks**

a) Decommissioning physically occurs after the end-of-life of the investment, and may be delayed by an optional lag period \textit{DLAG} (e.g. a “cooling off” of the process before dismantling may take place). The decommissioning costs follow the same patterns and rules as those for investment costs. In particular, the same four cases that were defined for investment costs are still applicable.

b) The same principles preside over the timing of payments of decommissioning costs as were defined for investment costs, namely, the decomposition of payments into a stream of payments extending over the economic life of decommissioning, \textit{DELIF}.

c) At decommissioning time, the recuperation of embedded materials is allowed by the model. This is treated as explained for investment costs, i.e. either as an explicit commodity flow, or as a credit (revenue) subtracted by the user from the decommissioning cost.

g) Decommissioning activities may also receive taxes or subsidies which are proportional to the corresponding decommissioning cost.

\[ EQ \_COSTDECOM(y) \ \
\text{\ if \ } y \in ALLYEARS \]

**Case 1.a)** If \( ILED_{i} \leq ILED_{Min,t} \) and \( TLIFE_{i} + ILED_{i} \geq D(t) \)

(Small divisible projects, non-repetitive, progressive investment in period)

In this case, decommissioning occurs exactly \( TLIFE+DLAG \) years after investment. For small projects (cases 1.a and 1.b), it is assumed that decommissioning takes exactly one year, and also that its cost is paid that same year (this is the same as saying that \( DLIFE=DELIF=1 \)). Any user-defined DLIFE/DELIF is in this case thus ignored. This is a normal assumption for small projects. As shown in the example below, also payments made at year \( y \) come from investments made at period \( T(y) \) or earlier. Hence the summation stops at \( T(y) \).

\[ INVDECOM(y) = \sum_{t=MILESTONES \cap PASTYEARS \cap T(y)} \text{INDIC}(1.a) \times \left( \frac{VAR \_ NCAP_{t}}{D(t)} + NCAP \_ PASTI_{t} \right) \times NCAP \_ DCOST_{y-TLIFE_{i}} \]

\[ \times \begin{cases} 1 & \text{if } M(t) - D(t) + 1 + TLIFE_{i} + DLAG_{i} \leq y \leq M(t) + TLIFE_{i} + DLAG_{i} \\ 0 & \text{otherwise} \end{cases} \]

(III.1.a)

**Comment:** Note that the cost attribute is indexed at the year when the investment started to operate. We have adopted this convention throughout the objective function.
Example III.1.a:
$D(t)=4$, $TLIFE=5$
$M(t)=B(t)+1$
$DLIFE=DELIF=1$

Investment:
Decommissioning
and payment

Case 1.b) if $ILED_t \leq ILED_{Min,t}$ and $TLIFE_t + ILED < D(t)$
(Small projects, repeated investments in period)

This cost expression is similar to I.1.b, but with payments shifted to the right by $TLIFE$ (see example). The inner summation disappears because of the assumption that $DELIF=1$. Note also that past investments have no effect in this case, because this case does not arise when $D(t)=I$, which is always the case for past periods.

$$INVDECOM(y) = \sum_{t \in \text{MILESTONES}} \text{INDIC}(1.b) \times \left(\frac{\text{VAR} - \text{NCAP}}{\text{TLIFE}_t}\right) \times \text{NCAP - DCOST}_y - \text{TLIFE}_t$$

$$\times\begin{cases} 1 & \text{if } B(t) + \left\lfloor \frac{\text{TLIFE}_t}{2} \right\rfloor \leq y \leq B(t) + \left\lfloor \frac{\text{TLIFE}_t}{2} \right\rfloor + C \cdot \text{TLIFE}_t - 1 \\ 0 & \text{otherwise} \end{cases}$$

where $C = \left\langle \frac{D(t)}{\text{TLIFE}_t} \right\rangle$

(III.1.b)
Case 2.a: $ILED_i > ILED_{Min,t}$ and $ILED_i + TLIFE_i \geq D(t)$
(Large, indivisible projects, unrepeated investment in period)

In this situation, it is assumed that decommissioning of the plant occurs over a period of time called $DLIFE$, starting after the end of the technical process life plus a time $DLAG$ (see example). $DLAG$ is needed e.g. for a reactor to “cool down” or for any other reason. Furthermore, the payments are now spread over $DELIF$, which may be larger than one year.

$$INVDECOM(y) = \sum_{t \in MILESTONES, t \leq T(y)} INDIC(2,a) \times \sum_{k = \text{Max}[B(t) + ILED_i, TLIFE_i + DLAG_i, DLAG_i, -1]}^{\text{Min}[y, B(t) + ILED_i, TLIFE_i, + DLAG_i, + DLAG_i, -1]} \left( \frac{VAR \times NCAP_i}{DLIFE_i} \right) \times CRF_i \times NCAP \_ DCOST_{B(t) + ILED_i}$$

$$+ \sum_{t \in PAST YEARS} INDIC(2,a) \times \sum_{k = \text{Max}[i + TLIFE_i, + DLAG_i, + DLAG_i, -1]}^{\text{Min}[y, i + TLIFE_i, + DLAG_i, + DLAG_i, -1]} \left( \frac{NCAP \_ PASTI_i}{DLIFE_i} \right) \times CRF_i \times NCAP \_ DCOST_i$$

(III.2.a)

Useful Range for $y$:
$\{B(t) + ILED_i + TLIFE_i + DLAG_i - 1, same + DELIF_i - 1\}$
Example II.2.a:

$D(t)=8$, $ILED=4$

$TLIFE=6$, $DLAG=2$, $DLIFE=3$

$DELIF=2$

Investment:
Decommissioning and payments
Decommissioning Payments only:

Case 2.b: $ILED_t > ILED_{Min,t}$ and $TLIFE_t + ILED_t < D(t)$
(Big projects, repeated investments in period)

Here too, the decommissioning takes place over $DLIFE$, but now, contrary to case 2.a, the process is repeated more than once in the period. The last investment has life extending over following periods, as in all similar cases. The resulting stream of yearly payments is complex, and therefore, we are forced to use an algorithm rather than a closed form summation. See also example below.

**ALGORITHM** (apply to each $t$ such that $t \leq T(y)$)

**Step 0:** Initialization

$p_t(y) := 0 \quad \forall \quad B(t) + ILED_t + TLIFE_t + DLAG_t \leq y \leq same + (C - 1) \times TLIFE_t + DLIFE_t + DELIF_t - 2$

Where:

$$C = \left\lfloor \frac{D(t) - ILED_t}{TLIFE_t} \right\rfloor$$
Step 1: Compute payment vector

For $I = 1$ to $C$

For $J = 1$ to $DLIFE_i$

For $L = 1$ to $DELIF_i$

$$P_i(B(t) + ILED_i + I \times TLIFE_i + DLAG_i + J + L - 2) =$$

same + $\frac{NCAP \_ DCOST_{B(t)+ILED_i+(I-1)+TLIFE_i}}{DLIFE_i}$

Next $L$

Next $J$

Next $I$

END ALGORITHM

$$INVDECOM(y) = \sum_{t \in MILESTONES, \ t \leq T(y)} INDIC(III.2.b) \times P_i(y) \times VAR \_ NCAP_i \times CRF$$

III.2.b

Example III.2.b:

$D(t)=13$, $ILED=4$

$TLIFE=5$, $DLAG=2$

$DLIFE=3$, $DELIF=2$

$C=2$

Construction

Decommissioning and Payment

Decommissioning Payment only
6.2.5 Fixed annual costs: FIXCOST(y), SURVCOST(y)

The fixed annual costs are assumed to be paid in the same year as the actual operation of the facility. However, the spreading of the investment described in subsection 5.1.1 results in a tapering in and a tapering out of these costs. Taxes and subsidies on fixed annual costs are also accepted by the model.

There are two types of fixed annual costs, FIXCOST(y), which is incurred each year for each unit of capacity still operating, and SURVCOST(y), which is incurred each year for each unit of capacity in its DLAG state (this is a cost incurred for surveillance of the facility during the lag time before its demolition). Again here, the same classification of cases is adopted as in previous subsections on capital costs. Note that by assumption, SURVCOST(y) occurs only in cases 2. DLAG is allowed to be positive even in case 1a, but that in this case the surveillance costs are assumed to be negligible. Finally, note that FIXCOST(y) need be computed only for years y within the planning horizon, whereas SURVCOST(y) may exist for years beyond the horizon.

**Remark on early retirements:**

In TIMES, any capacity may also be retired before the end of its technical lifetime, if so-called early retirements are enabled for a process. In such cases, the plant is assumed to be irrevocably shut down, and therefore fixed O&M costs would no longer occur. This situation is not taken into account in the standard formulations given below, but it has been taken into account in the model generator. To see that the expressions for the fixed annual costs, taxes and subsidies could be easily adjusted for early retirements, consider the standard expressions for \( \text{FIXCOST}(y) \), which can all be written as follows:

\[
\text{FIXCOST}(r, y) = \sum_{(r,v,t,p) \in \text{rip}} \left[ \text{VAR \_ NCAP}_{r,v,p} (\varnothing t_y) + \text{NCAP \_ PASTI}_{r,v,p} \right] \times CF_{r,v,p,y}
\]

Here, \( CF_{r,v,p,y} \) is the compound fixed cost coefficient for each capacity vintage in year \( y \), as obtained from the original expressions for \( \text{FIXCOST}(y) \). Recalling that fixed costs are accounted only within the model horizon, these expressions can be adjusted as follows:

\[
\text{FIXCOST}^{\circ}(r, y) = \sum_{(r,v,t,p) \in \text{rip}} \left[ \text{VAR \_ NCAP}_{r,v,p} (\varnothing t_y) + \text{NCAP \_ PASTI}_{r,v,p} - \sum_{\text{pre \_ reap}_{r,v,t,p}} \text{VAR \_ SCAP}_{r,v,t,p} \right] \times CF_{r,v,p,y}
\]

As one can see, the expressions for \( \text{FIXCOST}(r,y) \) can be augmented in a straightforward manner, obtaining the expressions \( \text{FIXCOST}^{\circ}(r,y) \) that take into account early capacity retirements of each vintage, represented by the \( \text{VAR \_ SCAP}_{r,v,t,p} \) variables.
Case 1.a) If  $ILED_t \leq ILED_{Min,t}$  and  $TLIFE_t + ILED_t \geq D(t)$
(Small projects, single investment in period)

$$EQ\_FIXCOST(y) , \quad y \leq EOH$$

The figure of the example shows that payments made in year $y$ may come from investments made at periods before $T(y)$, at $T(y)$ itself, or at periods after $T(y)$. Note that the cost attribute is multiplied by two factors: the $SHAPE$, which takes into account the vintage and age of the technology, and the $MULTI$ parameter, which takes into account the pure time at which the cost is paid (the notation below for $SHAPE$ and $MULTI$ is simplified: it should also specify that these two parameters are those pertaining to the $FOM$ attribute).

$$FIXCOST(y) =$$

$$\sum_{t\in MILESTONYR \cup PASTYEARS} INDIC(1.a) \times \sum_{v=\max[M(t)-D(t)+1,y-\max[TLIFE_t-1]]}^{\min(M(t),y)} \left( \frac{VAR - NCAP_t}{D(t)} + NCAP\_PASTI_t \right) \times NCAP\_FOM_v \times SHAPE(v, y-v) \times MULTI(y)$$

The useful range for $y$ is:
$\{ M(t) - D(t) + 1, M(t) + TLIFE_t - 1 \}$

and
$y \leq EOH \quad \text{(IV.1.a)}$

Example:

Example IV.1.a:
$D(t) = 4$, $TLIFE = 5$
$M(t) = B(t) + 1$

Investment and fixed cost payment:
Fixed Cost Payment only
Case 1.b, if $ILED_i \leq ILED_{\text{Min},t}$ and $TLIFE_t + ILED < D(t)$
(Small projects, repeated investments in period)

The figure shows that payments made at year $y$ may come from investments made at, before, or after period $T(y)$. Note that our expression takes into account the vintage and age of the FOM being paid, via the SHAPE parameter, and also the pure time via MULTI, both pertaining to the FOM attribute.

$$\text{FIXCOST}(y) = \sum_{t \in \text{MILESTONYR}} \text{INDIC} (1.b) \times \sum_{v=\text{Max}\left\{B(t) - TLIFE_t / 2, y - TLIFE_t + 1\right\}}^{\text{Min}\left\{y, \left( B(t) - TLIFE_t / 2\right) + C \times TLIFE_t - 1\right\}} \left( \frac{\text{VAR}_t \text{NCAP}_{\text{FOM}_y}}{\text{TLIFE}_t} \right) \times \text{NCAP}_t \text{FOM}_y$$

$$\times \text{SHAPE}(t, y - v) \times \text{MULTI}(y)$$

(IV.1.b)

where

$$C = \left\lfloor \frac{D(t)}{TLIFE_t} \right\rfloor$$

**Useful Range for $y$:**

$$\left\{ \left( B(t) - \frac{TLIFE_t}{2} \right), \left( B(t) - \frac{TLIFE_t}{2} \right) + (C + 1) \times TLIFE_t \right\}$$

and

$$y \leq EOH$$

Example:
Case 2.a: \( \text{ILED}_i > \text{ILED}_{\text{Min},t} \) and \( \text{ILED}_i + \text{TLIFE}_i \geq D(t) \)

(Large, indivisible projects, unrepeated investment in period)

i) \( \text{FIXCOST}(y) \)

The figure of the example shows that payments made in year \( y \) may come from investments made at period \( T(y) \) or earlier, but not later. Again here the \( \text{SHAPE} \) has the correct vintage year and age, as its two parameters, whereas \( \text{MULTI} \) has the current year as its parameter. Both pertain to \( \text{FOM} \).

\[
\text{FIXCOST}(y) = \sum_{t \in \text{MILESTONYR}, t \leq T(y)} \text{INDIC}(2.a) \times (\text{VAR}_\text{NCAP}_i) \times \text{NCAP}_\text{FOM} B(t)+\text{ILED}_i \\
\times \left\{ \begin{array}{ll}
1 & \text{if } B(t) + \text{ILED}_i \leq y \leq B(t) + \text{ILED}_i + \text{TLIFE}_i - 1 \\
0 & \text{otherwise}
\end{array} \right\} \times \text{SHAPE}(t, y - B(t) + \text{ILED}_i) \times \text{MULTI}(y)
\]

\[+ \sum_{t \in \text{PASTYEARS}} \text{INDIC}(2.a) \times (\text{NCAP}_\text{PASTI}_i) \times \text{NCAP}_\text{FOM}_i \\
\times \left\{ \begin{array}{ll}
1 & \text{if } t \leq y \leq t + \text{TLIFE}_i - 1 \\
0 & \text{otherwise}
\end{array} \right\} \times \text{SHAPE}(t, y - t) \times \text{MULTI}(y)
\]

(IV.2.a)

Useful Range for \( y \):

\[ \{ B(t) + \text{ILED}_i, B(t) + \text{ILED}_i + \text{TLIFE}_i - 1 \} \]

and

\( y \leq \text{EOH} \)

ii) \( \text{SURVCOST} \) (Surveillance cost for same case 2.a. See same example)

\[
\text{SURVCOST}(y) = \sum_{t \in \text{MILESTONYR}, t \leq T(y)} \text{INDIC}(2.a) \times (\text{VAR}_\text{NCAP}_i) \times \text{NCAP}_\text{DLAGC} B(t)+\text{ILED}_i \\
\times \left\{ \begin{array}{ll}
1 & \text{if } B(t) + \text{ILED}_i + \text{TLIFE}_i \leq y \leq B(t) + \text{ILED}_i + \text{TLIFE}_i + \text{DLAG}_i - 1 \\
0 & \text{otherwise}
\end{array} \right\}
\]
\[ + \sum_{t \in \text{PAST YEARS}} \text{INDIC}(2,a) \times (\text{NCAP}_i - \text{PASTI}_t) \times \text{NCAP}_i - \text{DLAGC}_i \]

\[
\begin{cases} 
    1 \text{ if } t + \text{TLIFE}_t \leq y \leq t + \text{TLIFE}_t + \text{DLAG}_t - 1 \\
    0 \quad \text{otherwise}
\end{cases}
\]

(IV.2.a’)

Useful Range for \( y \):
\[ \{B(t) + \text{ILED}_t + \text{TLIFE}_t, \text{ same } + \text{DLAG}_t - 1\} \]

Note that \( y \) may be larger than EOH

Example IV.2.a and IV.2.a’:
\( D(t) = 8, \text{ILED} = 4 \)
\( \text{TLIFE} = 6, \text{DLAG} = 2 \)

Remark: again here, the cost attribute is indexed by the year when investment started its life. Also, note that, by choice, we have not defined the \( \text{SHAPE} \) or \( \text{MULTI} \) parameters for surveillance costs.
Case 2.b: $ILED_t > ILED_{Min,t}$ and $TLIFE_t + ILED_t < D(t)$
(Big projects, repeated investments in period)

i. Fixed O&M cost

The cost expression takes into account the vintage and the age of the $FIXOM$ being paid at any given year $y$. See note in formula and figure for an explanation.

$$
\sum_{t \in \text{MILESTONES}, \tau \leq T(y)} \text{INDIC}(2.b) \times (\text{VAR}_-NCAP_t) \times NCAP_-FOM_{B(t)+ILED_t+I\cdot TLIFE_t} \times \text{SHAPE}(t, y - B(t) - ILED_t - I \cdot TLIFE_t) \times \begin{cases} 1 & \text{if } 0 \leq I \leq C - 1 \\ 0 & \text{otherwise} \end{cases}
$$

where:

$I = \left\{ \frac{y - B(t) - ILED_t}{TLIFE_t} \right\}$

I is the index of the investment cycle where $y$ lies. $I$ varies from 0 to $C-1$

and

$C = \left\{ \frac{D(t) - ILED_t}{TLIFE_t} \right\}$

Range for $y$:

$\{B(t) + ILED_t, B(t) + ILED_t + C \times TLIFE_t - 1\}$

and

$y \leq EOH$

Remark: same as above, concerning the indexing of the cost attribute

ii. $\text{SURVCOST}(y)$ (surveillance cost for same case; the same example applies)

$$
\text{SURVCOST}(y) = \sum_{t \in \text{MILESTONES}, \tau \leq T(y)} \text{INDIC}(2.b) \times (\text{VAR}_-NCAP_t) \times NCAP_-DLAGC_{B(t)+ILED_t+I\cdot TLIFE_t} \times \begin{cases} 1 & \text{if } B(t) + ILED_t + (I + 1) \times TLIFE_t \leq y \leq \text{same} + DLAG_t - 1 \text{ and } 0 \leq I \leq C - 1 \\ 0 & \text{otherwise} \end{cases}
$$
where:
\[ I = \left( \frac{y - B(t) - \text{ILED}_t - \text{TLIFE}_t}{\text{TLIFE}_t} \right) \]

and
\[ C = \left( \frac{D(t) - \text{ILED}_t}{\text{TLIFE}_t} \right) \]

*Note that \( y \) may exceed EOH*

**Example for IV.2.b and IV.2.b':**

\[ D(t)=13, \text{ILED}=4 \]
\[ \text{TLIFE}=5, \text{DLAG}=2 \]
\[ C=2 \]

*Remark:* same as precedently regarding the indexing of the cost attribute \( \text{NCAP}_{-DLAGC} \)

**6.2.6 Annual taxes/subsidies on capacity: FIXTAXSUB(Y)**

It is assumed that these taxes (subsidies) are paid (accrued) at exactly the same time as the fixed annual costs. Therefore, the expressions IV of subsection 5.1.4 are valid, replacing the cost attributes by \( \text{NCAP}_{-FTAX} - \text{NCAP}_{-FSUB} \).
6.2.7 Variable annual costs \( VARCOST(y), \ y \leq EOH \)

Variable operations costs are treated in a straightforward manner (the same as in MARKAL), assuming that each activity has a constant activity over a given period.

In this subsection, the symbol \( VAR_XXX \) is any variable of the model that represents an activity at period \( t \). Therefore, \( XXX \) may be \( ACT, FLO, COMX, COMT \), etc. Note that, if and when the technology is vintaged, the variable has an index \( v \) indicating the vintage year, whereas \( T(y) \) indicates the period when the activity takes place. Similarly, the symbol \( XXX\_COST \) represents the value in year \( k \) of any cost attribute that applies to variable \( VAR_XXX \).

Finally, the expressions are written only for the years within horizon, since past years do not have a direct impact on variable costs, and since no variable cost payments occur after EOH. Note also that the SHAPE and MULTI parameters are not applicable to variable costs.

As stated in the introduction, the payment of variable costs is constant over each period. Therefore, the expressions below are particularly simple.

\[
VARCOST(y) = VAR\_XXX_{v,T(y)} \times XXX\_COST_y \\
VARTAXSUB(y) = VAR\_XXX_{v,T(y)} \times (XXX\_TAX_y - XXX\_SUB_y) \\
y \leq EOH
\]  

(\text{VI})

6.2.8 Cost of demand reductions \( ELASTCOST(y) \)

When elastic demands are used, the objective function also includes a cost resulting from the loss of welfare due to the reduction (or increase) of demands in a given run compared to the base run. See PART I for a theoretical justification.

\[
ELASTCOST(y) = \sum_{j=1}^{COM\_STEP_{lo}} COM\_BPRICE_{T(y)} \times \left(1 - \frac{(j - 1/2) \times COM\_VOC_{lo,T(y)}}{COM\_STEP_{lo}}\right) \times \frac{1}{COM\_ELAST_{lo,T(y)}} \\
- \sum_{j=1}^{COM\_STEP_{up}} COM\_BPRICE_{T(y)} \times \left(1 + \frac{(j - 1/2) \times COM\_VOC_{up,T(y)}}{COM\_STEP_{up}}\right) \times \frac{1}{COM\_ELAST_{up,T(y)}} \\
y \leq EOH
\]  

(\text{VII})
6.2.9 Salvage value: SALVAGE (EOH+1)

Investments whose technical lives exceed the model’s horizon receive a SALVAGE value for the unused portion of their technical lives. Salvage applies to several types of costs: investment costs, sunk material costs, as well as decommissioning costs and surveillance costs. SALVAGE is reported as a single lump sum revenue accruing precisely at the end of the horizon (and then discounted to the base year like all other costs).

The salvaging of a technology’s costs is an extremely important feature of any dynamic planning model with finite horizon. Without it, investment decisions made toward the end of the horizon would be seriously distorted, since their full value would be paid, but only a fraction of their technical life would lie within the horizon and produce useful outputs.

What are the costs that should trigger a salvage value? The answer is: any costs that are directly or indirectly attached to an investment. These include investment costs and decommissioning costs. Fixed annual costs and variable costs do not require salvage values, since they are paid each year in which they occur, and their computation involves only years within the horizon. However, surveillance costs should be salvaged, because when we computed them in section 6.2.5, we allowed \( y \) to lie beyond EOH (for convenience). Finally, note that any capacity prematurely retired within the model horizon is not assumed to have a salvage value (although this detail is not explicitly shown in the formulation below).

Thus, SALVAGE is the sum of three salvage values

\[
SALVAGE(EOH + 1) = SALVINV(EOH + 1) + SALVDECOM(EOH + 1) + SALVSURV(EOH + 1)
\]

We treat each component separately, starting with SALVINV.

A). Salvaging investment costs (from subsections 6.2.2 and 6.2.3)

The principle of salvaging is simple, and is used in other technology models such as MARKAL, etc: a technology with technical life \( TLIFE \), but which has only spent \( x \) years within the planning horizon, should trigger a repayment to compensate for the unused portion \( TLIFE-x \) of its active life. The computation of the salvage value obeys a simple rule, described by the following result:
Result 1

The salvage value (calculated at year $k$) of a unit investment made in year $k$, and whose technical life is $TL$, is:

$$S(k, TL) = 0 \quad \text{if } k + TL \leq EOH$$

$$S(k, TL) = 1 \quad \text{if } k > EOH$$

$$S(k, TL) = \frac{(1 + d)^{TL - EOH - 1 + k} - 1}{(1 + d)^{TL} - 1} \quad \text{otherwise}$$

where $d$ is the general discount rate.

Note that the second case may indeed arise, because some investments will occur even after $EOH$.

Since we want to calculate all salvages at the single year $(EOH+1)$, the above expressions for $S(k,TL)$ must be discounted (multiplied) by:

$$(1 + d)^{EOH+1-k}$$

Finally, another correction must be made to these expressions, whenever the user chooses to utilize a technology specific discount rate. The correction factor which must multiply every investment (and of course every salvage value) is:

$$CRF = \frac{\left(1 - \frac{1}{1 + i_s}\right) \times \left(1 - \frac{1}{(1 + i)^{ELIFE}}\right)}{\left(1 - \frac{1}{1 + i}\right) \times \left(1 - \frac{1}{(1 + i_s)^{ELIFE}}\right)}$$

where $i$ is the general discount rate

$i_s$ is the technology specific discount rate

and $ELIFE$ is the economic life of the investment

Note: the time indexes have been omitted for clarity of the expression.

The final result of these expressions is Result 2 expressing the salvage value discounted to year $EOH+1$, of a unit investment with technical life $TL$ made in year $k$ as follows. Result 2 will be used in salvage expressions for investments and taxes/subsidies on investments.
These expressions may now be adapted to each case of investment (and taxes/subsidies on investments). We enumerate these cases below. Note that to simplify the equations, we have omitted the second argument in \( SAL \) (it is always \( TLIFE_i \) in the expressions).

**Case 1.a** \( ILED_i \leq ILED_{Min,i} \) and \( TLIFE_i + ILED_i \geq D(t) \)

(Small divisible projects, non-repetitive, progressive investment in period)

\[
SALINV(EOH + 1) = \sum_t INDIC(I.1.a) \times \sum_{v=M(t) - D(t) + 1}^{B(t) - TL_i / 2 + C_i - TLIFE_i - 1} \left( \frac{VAR - NCAP}{D(t)} + NCAP_{-PASTI_i} \right) \times NCAP_{-COST_v} \times SAL(v)
\]

where \( SAL(v) \) is equal to \( SAL(v,TLIFE_i) \) defined in Result 2.

Note that \( SAL(v) = 0 \) whenever \( v + TLIFE_i \leq EOH + 1 \) (see Result 2)

\[(VIII.1.a)\]

**Case 1.b** \( ILED_i \leq ILED_{Min,i} \) and \( TLIFE_i + ILED < D(t) \)

Small Projects, repeated investments in period

\[
SALINV(EOH + 1) = \sum_t INDIC(I.1.b) \times \sum_{v=B(t) - TL_i / 2 + C_i - TLIFE_i}^{v = B(t) - TL_i / (C_i - 1) - TLIFE_i - 1} \frac{VAR - NCAP}{TLIFE_i} \times NCAP_{-COST_v} \times SAL(v)
\]

Note again here that \( SAL(v) \) equals 0 if \( v + TLIFE \leq EOH + 1 \)

\[(VIII.1.b)\]
**Case 2.a:** \( ILED_j > ILED_{Min,t} \) and \( ILED_j + TLIFE_j \geq D(t) \)

(Large, indivisible projects, unrepeated investment in period)

\[
SALVINV EOH+1 = \sum_{t=MILESTONESYEARS} \text{VAR }_t \times NCAP_t \times NCAP \times COST \times B(t) \times ILED_j \times SAL(B(t) + ILED_j) \\
\]

*Note that* \( SAL(B(t) + ILED_j) = 0 \) whenever \( B(t) + ILED_j + TLIFE_j \leq EOH + 1 \)

*(VIII.2.a)*

**Case 2.b:** \( ILED > ILED_{Min,t} \) and \( TLIFE_j + ILED_j < D(t) \)

(Large, indivisible Projects, repeated investments in period)

\[
SALVINV EOH+1 = \sum_{t} \text{VAR }_t \times NCAP_t \times NCAP \times COST \times B(t) \times (C-1) \times TLIFE_j \times ILED_j \times SAL(B(t) + (C-1) \times TLIFE_j + ILED_j) \\
\]

*Note again that* \( SAL(B(t) + (C-1) \times TLIFE_j + ILED_j) = 0 \) whenever \( B(t) + (C-1) \times TLIFE_j + ILED_j + TLIFE_j \leq EOH + 1 \)

*(VIII.2.b)*

**NOTE:** salvage cost of taxes/subsidies on investment costs are identical to the above, replacing NCAP_COST by \{NCAP_ITAX – NCAP_ISUB\}.

**B). Savage value of decommissioning costs (from subsection 6.2.4)**

For decommissioning costs, it should be clear that the triggering of salvage is still the fact that some residual life of the investment itself exists at \( EOH + 1 \). What matters is not that the decommissioning occurs after EOH, but that some of the investment life extends beyond EOH. Therefore, Result 1 derived above for investment costs, still applies to decommissioning. Furthermore, the correction factor due to the use of technology specific discount rates is also still applicable (with \( ELIFE \) replaced by \( DELIF \)).

However, the further discounting of the salvage to bring it to \( EOH + 1 \) is now different from the one used for investments. The discounting depends on the year \( l \) when the decommissioning occurred and is thus equal to:

\[(1 + d)^{EOH+1-l} \text{ where } l \text{ is the year when decommissioning occurs.}\]

\( l \) depends on each case and will be computed below

In cases 1.a and 1.b, \( l = TLIFE + k \)
In case 2.a  

\[ k \text{ is fixed at } B(t)+ILED, \text{ but } l \text{ varies from } (B(t)+ILED+TLIFE+DLAG) \text{ to } (\text{same } + DLIFE–1) \]

In case 2.b  

\[ k \text{ is fixed at } B(t)+ILED+(C–1)\times TLIFE, \text{ but } l \text{ varies } \text{from } (B(t)+ILED+C\times TLIFE+DLAG) \text{ to } (\text{same } + DLIFE–1) \]

It is helpful to look at the examples for each case in order to understand these expressions.

Finally, the equivalent of Result 2 is given as Result 3, for decommissioning.

<table>
<thead>
<tr>
<th>Result 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Salvage Value of a decommissioning cost occurring at year ( l ), for an investment taking place at year ( k ), is:</td>
</tr>
</tbody>
</table>
| \[
SAL(k,l) = 0 \quad \text{if } k + TL \leq EOH
\]
| \[
SAL(k,l) = \frac{CRF_s}{CRF} \times (1+i)^{EOH+1-l} \quad \text{if } k \geq EOH + 1
\]
| \[
SAL(k,l) = \frac{(1+d)^{TLIFE+k-l} - (1+d)^{EOH+1-l}}{(1+d)^{TLIFE} - 1} \times \frac{CRF_s}{CRF} \quad \text{otherwise}
\]

where \( d \) is the general discount rate 
and \( d_s \) is the technology specific discount rate

We are now ready to write the salvage values of decommissioning cost in each case.
Case 1.a \( ILED_i \leq ILED_{\text{Min},t} \) and \( \text{TLIFE}_i + ILED_i \geq D(t) \)
(Small divisible projects, non-repetitive, progressive investment in period)

\[
\text{SALVDECOM} (EOH + 1) = \sum_{i} \text{INDIC}(1.a) \times \sum_{v = M(t) - D(t) + 1}^{M(t)} \left( \frac{\text{VAR} - \text{NCAP}_t}{D(t)} + \text{NCAP} \_ \text{PASTI}_t \right) \times \\
\text{NCAP} \_ \text{DCOST}_v \times \text{SAL}(v, v + \text{TLIFE}_i)
\]

where \( \text{SAL}(k, l) \) is defined in Result 3.

Note that \( \text{SAL}(v, x) \) is always 0 whenever \( v + \text{TLIFE} \leq EOH + 1 \) \( \text{(IX.1.a)} \)

Case 1.b \( ILED_i \leq ILED_{\text{Min},t} \) and \( \text{TLIFE}_i + ILED < D(t) \)
(Small Projects, repeated investments in period)

\[
\text{SALVDECOM} (EOH + 1) = \sum_{i} \text{INDIC}(1.b) \times \sum_{v = B(t) - 1}^{B(t) - 1 + C - TLIFE} \frac{\text{VAR} - \text{NCAP}_t}{\text{TLIFE}_t} \times \\
\text{NCAP} \_ \text{DCOST}_v \times \text{SAL}(v, v + \text{TLIFE}_i)
\]

Note again here that \( \text{SAL}(k, l) \) equals 0 if \( k + \text{TLIFE} \leq EOH + 1 \) \( \text{(IX.1.b)} \)

Case 2.a: \( ILED_i > ILED_{\text{Min},t} \) and \( ILED_i + \text{TLIFE}_i \geq D(t) \)
(Large, indivisible projects, unrepeated investment in period)

\[
\text{SALVDECOM} (EOH + 1) = \sum_{t = \text{MILESTONESYEARS}} \text{INDIC}(2.a) \times \text{VAR} \_ \text{NCAP}_t \times \\
\text{NCAP} \_ \text{COST}_{B(t) + ILED_i} \times \sum_{\text{same} = \text{DLIFE} - 1}^{\text{BLAG}} \text{SAL}(B(t) + ILED_i, l)
\]

Note that \( \text{SAL} \) is 0 whenever \( B(t) + ILED_i + \text{TLIFE}_i \leq EOH + 1 \) \( \text{(IX.2.a)} \)
Case 2.b: \( \text{ILED}_t > \text{ILED}_{\text{Min},t} \) and \( \text{TLIFE}_t + \text{ILED}_t < \text{D}(t) \) 

(Large, indivisible Projects, repeated investments in period)

\[
\text{SALVDECOM}(EOH + 1) = \sum_{t = \text{MILESTONEMEASURES}} \text{INDIC}(2.b) \times \text{VAR}_\text{NCAP}_t \times \text{NCAP}_\text{DCOST}_{B(t) + (C - 1) \times \text{TLIFE}_t + \text{ILED}_t} \\
\times \sum_{l = B(t) + \text{ILED}_t + C > \text{TLIFE}_t + \text{DLAG}_t} \text{SAL}[B(t) + \text{ILED}_t + (C - 1) \times \text{TLIFE}_t, l]
\]

where

\[
C = \left( \frac{D(t) - \text{ILED}_t}{\text{TLIFE}_t} \right)
\]

Note again that \( \text{SAL} \) is 0 whenever \( B(t) + C \times \text{TLIFE}_t + \text{ILED}_t \leq EOH + 1 \)  

(IX.2.b)

C) Salvage Value of Surveillance Costs

Similarly to the salvaging of decommissioning costs, the basic salvage value fractions \( S(k,m) \) defined in \textit{Result 1} at the beginning of Section 6.2.9 are used as the basis for the salvage value of surveillance costs. However, unlike with decommissioning costs, there is no need to make corrections for technology-specific discount rates, as the costs do not represent capital costs. In addition, the discounting to \( EOH + 1 \) must be made separately for each surveillance year. Note that only Cases 2 have surveillance costs.

Case 2.a: \( \text{ILED}_t > \text{ILED}_{\text{Min},t} \) and \( \text{ILED}_t + \text{TLIFE}_t \geq \text{D}(t) \) 

(Large, indivisible projects, unrepeated investment in period)

\[
\text{SALVSURV}(EOH + 1) = \sum_{t = \text{MILESTONEMEASURES}} \text{INDIC}(2.a) \times S(B(t) + \text{ILED}_t, \text{TLIFE}_t) \times \\
\text{VAR}_\text{NCAP}_t \times \text{NCAP}_\text{DLAGC}_{B(t) + \text{ILED}_t} \times \sum_{l = B(t) + \text{ILED}_t + \text{TLIFE}_t} \text{DISC}(l, EOH + 1)
\]

Note that \( S(k,m) = 0 \) whenever \( k + m \leq EOH + 1 \).  

(X.2.a)
Case 2.b: \( ILED_i > ILED_{\text{Min},i} \) and \( TLIFE_i + ILED_i < D(t) \)

(Large, indivisible projects, repeated investments in period)

\[
SALVSURV(EOH + 1) =
\]

\[
\sum INDIC(2.b) \times S[B(t) + ILED_i + (C - 1) \times TLIFE_i] \times \text{VAR}_N \times \text{NCAP}_i \times \text{NCAP}_D \times \text{DLAG} \times \text{VAR}_N \times \text{NCAP}_C \\
\sum \text{DISC}(l, EOH + 1)
\]

where : \( C = \frac{D(t) - ILED_i}{TLIFE_i} \)

Note again that \( S(k, m) = 0 \) whenever \( k + m \leq EOH + 1 \).

(X.2.b)

6.2.10 Late revenues from endogenous commodity recycling after EOH

\( \text{LATEREVENUE}(y) \)

Late revenues consist of revenues from any materials and energy which had been embedded in some processes, and which are released after \( EOH \). Such revenues exist only if an exogenous salvage value was declared by the user for the sunk material.

Note: For materials released within the horizon, the revenue is either explicit (and then it is the user’s responsibility to indicate a negative cost – credit – at dismantling time), or the revenue is implicit, and then the user must specify a physical release of the material at dismantling time, and the model will correctly ‘price’ this material within the RES.

\( \text{LATEREVENUES}(y) \quad y \geq EOH+1 \)

The late revenues come only from the resale at dismantling time, of materials and/or energy that were sunk at construction time. Therefore, the \( \text{LATEREVENUES} \) expressions are identical to the decommissioning cost expressions, with the NCAP_DCOST attribute replaced by

\[
\sum_{c} -\text{NCAP}_V(c) \times \text{NCAP}_O(c)
\]

where the summation extends over all commodities \( c \) for which an \( \text{NCAP}_O \) attribute is defined (defaults to zero if undefined)

\( \text{LATEREVENUES}(y) \) is reported as a lump sum discounted to the user selected base year.
6.2.11 Known issues in the standard objective function formulation

There are a few known issues in the standard objective function formulation that may cause small distortions in the cost accounting and, subsequently, in the relative competitiveness of technologies. The distortions only occur when using period lengths $D(t) > 1$. The issues can be briefly summarized as follows:

- In the investment cases 1.a and 1.b, the timing of the annual payments for the investment costs and fixed operation and maintenance costs are not fully in sync with the assumed amounts of available capacity. Although the effective difference is usually quite small, with longer periods having an even number of years, the distortion may become considerable.

- In the investment cases 1.a and 1.b, the spreading of the investment cost over $D(t)$ or $TLIFE(p)$ years causes some distortions in the salvage value accounting, which are at the highest in cases where $B(v) + TLIFE = EOH + 1$, (capacity is retired exactly at the end of the horizon), because in such cases the capacity is assumed fully available within the model horizon, but it still has a salvage value according to the standard formulation.

- In all investment cases, the capacity is assumed to be available in each period according to the proportion of the period being covered by the years $[B(v) + ILED(v), B(v) + ILED(v) + TLIFE(v) – 1]$. If all periods contain only a single year, this is quite accurate, but, due to discounting, it is no longer accurate with longer periods. That is because any capacity available in year $y$ has a larger value than the same capacity available in year $y+1$. But again, this causes only a small distortion in the cost accounting.

- With variable period lengths, investments for period $t$ can start even before the previous milestone year $t-1$. If the investment costs are changing over time, in such cases the costs are not accounted in a fully consistent way, because the investment cost data is taken from the start year of each investment step.

The first three of these issues have been addressed by introducing an optional switch ($SET OBLONG YES$), which, when activated, will eliminate all those three issues. For the first two issues, the discounting of the annual payments for the investment costs and fixed operation and maintenance costs is slightly modified, such that the weighted average of the commissioning years over the investment steps is exactly equal to $B(v)$ (the weights being the present value factors for the commissioning years). In other words, the modification introduces a small additional discounting multiplier, which moves the whole investment spread slightly in time, such that the resulting costs will effectively always be in sync with the assumed available capacity (and activity).

For the third issue, the capacity transfer coefficients are slightly modified to reflect the true value of the capacity in each period, based on the discounted proportion of the period being covered by the process lifetime.

The modified objective function has been verified to produce results that are fully consistent with single-year period results, assuming that process parameters do not change over time, which is the best what one can expect. The fourth issue can only be
addressed by using any of the alternative objective formulations (see separate *Objective Function Variants* documentation, available at the ETSAP documentation website).

### 6.2.12 The discounting methods for annual payments

In the standard objective function of TIMES, all costs and payments are assumed to occur at the beginning of each year. In the case of investment costs, this means that the annualized payments made in the beginning of each year within the economic lifetime are equivalent to a lump-sum investment cost paid at the beginning of the first operation year, if the annual payments are discounted back to that point by the technology-specific discount rate (for instance, in case 1a, each lump sum is equal to \(NCAP\_COST/D(t)\)). Similarly, in the case of operation costs (e.g. \(NCAP\_FOM\)), the total annual costs are assumed to occur at the beginning of each operating year.

Because the operating costs can nevertheless be assumed to be spread continuously throughout the year, this kind of ‘beginning-of-year’ discounting method introduces a small bias in the discounting of different cost components. For example, the operating costs in the first year of operation should be assumed to occur about half a year later in time compared to the investment, and not at the same time, as assumed in TIMES. One may well argue that this time-difference should be reflected in the discounting applied.

In TIMES, there is an option to correct this small bias by using mid-year discounting, or even end-of-year discounting. The options can be activated by the switch \(MID\_YEAR/DISCSHIFT\) (see Part III, Control switches). The modifications needed in the discounting are basically quite similar for employing both mid-year and end-of-year discounting. Therefore, only the corrections for mid-year discounting are described in detail below.

The corrections needed for employing mid-year discounting in TIMES can be made in the following two steps:

1. First, simply assume that instead of the beginning of each year, all payments are made in the mid-point of each year in TIMES. As such, this assumption doesn't change the objective function in any way; it is only a change in thinking. However, it also means that instead of the beginning of the base year, all costs are assumed to be discounted to the mid-point of the base year.
2. Second, make the necessary corrections to the discounting of all those cost components that cannot be assumed to be actually paid at the mid-point of the year.

By going through the various cost components, the following conclusions hold for step 2:

- All variable, fixed operation and surveillance costs can be assumed to be paid in the mid-point of each year, and no change is needed for them in the discounting.
- The lump-sum investment costs in Cases 1 (\(NCAP\_COST/D(T)\)) should be assumed to occur at the beginning of the investment year instead of the mid-point.
- All the lump-sum investment costs in Cases 2 (\(NCAP\_COST/ILED\)) can be assumed to occur in the mid-point of each construction year. Therefore, no change is needed in the discounting of the annualized investment payments.
- Decommissioning costs in Cases 1 can be assumed to be paid in the mid-point of the year, because in these cases decommissioning is assumed to take exactly one year, and one may assume that, on the average, the costs occur at the mid-point.
• The lump-sum decommissioning costs in Cases 2 ($NCAP_{DCOST}/DLIFE$) can be assumed to occur at the mid-point of each year within the decommissioning lifetime. Therefore, no change is needed in the discounting of the annualized payments.

Consequently, the initial overall conclusion is that the only correction needed in the discounting of various cost components is related to the investment costs in Cases 1. If we assume that the Capital Recovery Factor used in the beginning-of-year discounting ($CRF_{beg}$) is still valid for mid-year discounting, we should simply shift the position of both the lump-sum investment and the annualized payments half a year backwards. In terms of discounting, this means that in Cases 1 the annualized investment payments should be multiplied by the factor $(1+d(y))^{0.5}$, where $d(y)$ is the general discount rate. Perhaps the simplest way to apply this correction in the objective function is to make the adjustment to the Capital Recovery Factor. Thus, for Cases 1 we could define a 'CRF corrected for mid-year discounting' ($CRF_{1,mid}$) as follows:

$$CRF_{1,mid} = CRF_{beg} \times (1+d(T(y)))^{0.5}$$

However, one could additionally argue that the Capital Recovery Factor $CRF_{beg}$ is no longer valid for mid-year discounting. The annualized investment payments can also be assumed to represent a continuous stream of costs, which should thus be assumed to be paid at the mid-point of each year. The shortcoming of the original $CRF_{beg}$ can be seen by calculating its value for an investment with an economic lifetime of just one year. The value of $CRF_{beg}$ is in this case exactly 1, although it seems obvious that some interest should be involved as well. Assuming that the single payment represents a continuous stream of costs, the payment can be assumed to occur at the mid-point of the year, and would thus include interest for half-year's time.

Accordingly, we should correct the definition of the CRF proper by assuming that the annualized payments occur half a year forward in time with respect to the lump-sum investment, which means that we must increase the nominal size of the payments by the corresponding interest for the half-year's time. Combining these corrections together, the general discount rate $d(y)$ should be simply replaced by the technology-specific discount rate $d_s(T(y))$ in the expression above, because in addition to the nominal change in the CRF, the time of the annualized payments has been restored back to original. However, to maintain consistency between Cases 1 and 2, the same basic correction to the CRF proper should be applied to all cases. Therefore, the total adjustments needed when taking into account the correction to the CRF proper are the following:

$$CRF_{prop_{mid}} = CRF_{beg} \times (1+d_s(T(y)))^{0.5}$$  \hspace{1cm} (XI.1)

$$CRF_{1,mid} = CRF_{prop_{mid}} \times (1+d(T(y)))^{0.5} \times (1+d(T(y)))^{-0.5} = CRF_{beg} \times (1+d_s(T(y)))^{0.5}$$  \hspace{1cm} (XI.2)

$$CRF_{2,mid} = CRF_{prop_{mid}} \times (1+d(T(y)))^{-0.5} = CRF_{beg} \times (1+d(T(y)))^{-0.5} \times (1+d_s(T(y)))^{0.5}$$  \hspace{1cm} (XI.3)

Consequently, in both cases the annualized investment payments are then assumed to occur at the mid-point of each fiscal year starting at the time of the lump-sum investment, and
the annual payments are equivalent to the lump-sum investment when discounted back to that point by the technology-specific discount rate. The implementation of the optional corrections for mid-year discounting corresponds to equations (XI.1 to XI.3). To be consistent, the expression (XI.3) for $CRF_{2,mid}$ should also be used for decommissioning costs.
6.3 Constraints

The constraints available in standard TIMES are shown in Table 23 below, and later fully described in the following subsections. The constraints related to the Climate Module (CLI), Damage Cost Functions (DAM) and Endogenous Technology Learning (ETL) are shown and described in three separate chapters (Appendices A, B and C respectively).

Table 24. List of TIMES equations

<table>
<thead>
<tr>
<th>Equation Name</th>
<th>Short description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BND_ELA</td>
<td>Upper bound on each of the step variables used to linearize the demand function when elastic demand feature is used</td>
</tr>
<tr>
<td>EQ(1)_ACTBND</td>
<td>Bound on the activity of a process</td>
</tr>
<tr>
<td>EQE_ACTEFF</td>
<td>Equality relationship that defines the activity efficiency of a process</td>
</tr>
<tr>
<td>EQ_ACTFLO</td>
<td>Equality relationship that defines the activity of a process in terms of its flow variables</td>
</tr>
<tr>
<td>EQ_ACTPL</td>
<td>Defines the efficiency deterioration of a process at partial loads</td>
</tr>
<tr>
<td>EQ_ACTRAMP</td>
<td>Defines bounds on the ramping of process activity, in proportion to its online capacity, in either direction (LO/UP)</td>
</tr>
<tr>
<td>EQL_ACTUPC</td>
<td>Sets a lower limit on the successive on-line / off-line hours of capacity</td>
</tr>
<tr>
<td>EQE_ACTUPS</td>
<td>Expresses that the change in process on-line capacity between successive timeslices must be equal to the capacity started-up – shut-down</td>
</tr>
<tr>
<td>EQL_ACTUPS</td>
<td>Expresses that the sum of process started-up capacity over a cycle must be at least equal to the max. amount of capacity put off-line in the cycle</td>
</tr>
<tr>
<td>EQ(1)_ASHAR</td>
<td>Establishes advanced share constraints between process flows</td>
</tr>
<tr>
<td>EQ(1)_BLND</td>
<td>Special blending constraints used to specify the composition of refined oil products</td>
</tr>
<tr>
<td>EQ_BNDCST</td>
<td>Establishes a variable representing the cumulative amount of process costs, taxes and/or subsidies over a time interval, for defining a bound</td>
</tr>
<tr>
<td>EQ(1)_BNDNET</td>
<td>Bound on the net amount (production minus consumption) of a commodity</td>
</tr>
<tr>
<td>EQ(1)_BNDRD</td>
<td>Bound on the total production of a commodity</td>
</tr>
<tr>
<td>EQ(1)_CAFLAC</td>
<td>Relates the flows in the primary group of a process to its available capacity; may be rigid (=) or flexible (≤)</td>
</tr>
<tr>
<td>EQ(1)_CAPACT</td>
<td>Relates the activity of a process to its available capacity; may be rigid (=) or flexible (≤,≥)</td>
</tr>
<tr>
<td>EQL_CAPFLO</td>
<td>Relates a flow not in the primary group of a process to its available capacity; only an upper bound for the flow ≤ is supported</td>
</tr>
<tr>
<td>EQ_CAPLOAD</td>
<td>Relates the activity of a process to its available on-line capacity in each timeslice; only for processes with flexible availability (≤,≥)</td>
</tr>
<tr>
<td>EQ(1)_CPT</td>
<td>Calculates the current capacity of a process in terms of all past and current investments in that process</td>
</tr>
<tr>
<td>EQ(1)_COMBAL</td>
<td>Balance equation of a commodity</td>
</tr>
<tr>
<td>EQE_COMPRD</td>
<td>Definition of the total production of a commodity</td>
</tr>
<tr>
<td>EQ_CUMFLO</td>
<td>Bound on the cumulative flow or activity of a process over a time interval</td>
</tr>
<tr>
<td>EQ_CUMNET</td>
<td>Bound on the cumulative production of a commodity over a time interval</td>
</tr>
<tr>
<td>EQ_CUMPRD</td>
<td>Bound on the cumulative net quantity of a commodity over a time interval</td>

<td>For a given process, expresses that the inflow of a commodity is tied to the total inflows of all commodities in a certain group</td>
</tr>
<tr>
<td>EQ(I)_OUTSHR</td>
<td>For a given process, expresses that the outflow of a commodity is tied to the total outflows of all commodities in a certain group</td>
</tr>
<tr>
<td>EQ_PEAK</td>
<td>Expresses that capacity available must exceed demand of a selected commodity in any time slice by a certain margin</td>
</tr>
<tr>
<td>EQ_PTRANS</td>
<td>Establishes an equality relationship between (groups of) inputs and certain (groups of) outputs of a process</td>
</tr>
<tr>
<td>EQL_SCAP</td>
<td>Bounds the amount of capacity salvaged if early retirements are active.</td>
</tr>
<tr>
<td>EQ_STGAUX</td>
<td>Establishes an equality relationship between storage main flows or activity and an auxiliary storage flow</td>
</tr>
<tr>
<td>EQ_STGIPS</td>
<td>Ensures the storage of a commodity between two time periods</td>
</tr>
<tr>
<td>EQ_STGTSS</td>
<td>Ensures the storage of a commodity between two timeslices</td>
</tr>
<tr>
<td>EQ(I)_STGIN</td>
<td>Bounds the input into a storage process</td>
</tr>
<tr>
<td>EQ(I)_STGOUT</td>
<td>Bounds the output of a storage process</td>
</tr>
<tr>
<td>EQ_STSDBAL</td>
<td>Defines balances between timeslice levels in a general timeslice storage</td>
</tr>
<tr>
<td>EQ(I)_UCRTP</td>
<td>Defines a dynamic bound on the growth / decay in the installed capacity, new capacity or activity of a process over successive periods</td>
</tr>
</tbody>
</table>

**User Constraints of the LHS type**

- User defined constraints that have a user defined constant RHS

**Timeslice-dynamic User Constraints**

- User defined constraints that involve only a single region \( r \) and period \( t \) but both timeslice \( s \) and the preceding timeslice \( s - rs_stg(r,s) \)

**User Constraints of dynamic type \((t,t+1)\)**

- User defined constraints that involve both period \( t \) and the succeeding period \( t+1 \)

**User Constraints of dynamic type \((t-1,t)\)**

- User defined constraints that involve both period \( t \) and the preceding period \( t-1 \)
6.3.1 Bound: BND_ELAST

Indices: region (r), year (t), commodity (c), time slice (s), linearization step (j),
direction of elastic demand change (l)

Type: ≤

Related variables: VAR_ELAST

Related equations: EQ(l)_COMBAL, EQ_OBJELS, EQ_OBJ

Purpose: Upper Bounds on the step variables used to represent the demand when the
elasticity is non-zero.

Remarks:

- These bounds are applied whenever a demand is price elastic, i.e. when the
  COM_ELAST (elasticity) and COM_VOC (total range) parameters are specified and not
  zero.
- If COM_ELAST and COM_VOC are specified, and COM_STEP (number of steps) is
  not, the latter defaults to 1 (single step discretization)
- Attributes COM_VOC and COM_STEP do not have a timeslice index. The user can still
  control elasticities in each time slice through COM_ELASTs.

Bound:

$$BND\_ELAST_{r,t,c,s,j,l} \geq COM\_STEP_{r,t,c} \land (s \in com\_ts_{r,t,c})$$

$$VAR\_ELAST_{r,t,c,s,j,l} \leq \frac{COMP\_PROJ_{r,t,c} \times COM\_FR_{r,t,c,s} \times COM\_VOC_{r,t,c,l}}{COM\_STEP_{r,t,c,l}}$$
6.3.2 Equation EQ(l)_ACTBND

Indices: region (r), model year (t), process (p), time slice (s)

Type: Any type, as determined by the index bd of ACT_BND:
- \( l = 'G' \) for \( bd = 'LO' \) (lower bound) yields \( \geq \).
- \( l = 'E' \) for \( bd = 'FX' \) (fixed bound) yields \( = \).
- \( l = 'L' \) for \( bd = 'UP' \) (upper bound) yields \( \leq \).

Related variables: VAR_ACT

Related equations: EQ_COMBAL, EQ_ACTFLO, EQ_PTRANS

Purpose: This equation bounds the total activity of a process in a period independently of the vintage years of the installed capacities. The equation will either be generated when the activity bound is specified for a timeslice being at a timeslice level above the timeslice level of the process (prc_tsl), e.g. ACT_BND is specified for an ANNUAL timeslice but the process operates on a DAYNITE timeslice level, or irrespectively of the timeslices when the process is characterized as a vintaged one (prc_vint). If activity bounds are specified for timeslices below the process timeslice level (prc_tsl), the bounds will be aggregated to the process timeslice level by standard aggregation (see Section 3.1.2) and then directly applied to the activity variable for non-vintaged processes. The same is true for activity bounds specified at the process timeslice level of non-vintaged processes.

Remarks:
- The equation is required because for the two cases described above (bound specified for a timeslice above the process timeslice level or process is characterized as a vintaged one), no single variable exists which can be bounded directly.
- The bound is only directly applied to VAR_ACT for non-vintaged processes, when ACT_BND is applied at the level prc_ts(r,p,s).

Interpretation of the results:
Primal: The level value of the equation describes the activity of the process in the considered period \( t \) and timeslice \( s \).
Dual: The dual variable describes in the case of a lower (upper) bound the cost increase (decrease) caused by an increase of the activity bound by one unit.
6.3.3 Equation: EQE_ACTEFF

Indices: region (r), vintage year (v), period (p), process (p), commodity group (cg), side (io), timeslice (s)

Type: =

Related variables: VAR_ACT, VAR_FLO

Related equations: EQ_PTRANS, EQ_ACTPL

Purpose: This equation is generated when the process activity efficiency has been defined with the input attribute $ACT_{EFF}_{r,v,p,cg,s}$ for a group of flows on the shadow side.

Remarks:
- The group cg in the equation may be either directly specified in ACT_EFF, or, if $ACT_{EFF}$ is only specified for single commodity, determined as the commodity type, or, if $ACT_{EFF}$ is specified for the reserved group name 'ACT', determined as the default shadow group of the process.
- The parameter $ACT_{EFF}_{r,v,p,cg,s}$ can be specified using any of the following as the cg:
  - commodity groups; these define a common efficiency for all member commodities in the group that are on the shadow side of the process;
  - commodity types (NRG/MAT/ENV/DEM/FIN); as above, these define a common efficiency for all member commodities in the group that are on the shadow side of the process;
  - the predefined commodity group 'ACT'; this defines a common efficiency for all members of the default shadow group of the process;
  - single commodities on the shadow side without an associated group efficiency; these define commodity-specific efficiencies, and the shadow group will consist of all commodities of the same type; if no commodity efficiency is defined for some member in the group, the default efficiency 1 is assumed;
  - single commodities on the shadow side with an associated group efficiency; these define commodity-specific efficiencies as above, but are multiplied by the efficiency specified for the group; if no efficiency is defined for some member in the group, the group efficiency is applied directly to that member;
  - single commodities C that are members of the PCG of the process; these define commodity-specific multipliers for the process efficiency when producing the commodity C; if no efficiencies are additionally defined on the shadow side of the process, the whole standard shadow group of the process is assumed to be involved in the transformation (as when using ‘ACT’), with the default efficiency of 1 on the shadow side.
- The ACT_EFF parameter can also be shaped by using a FLO_FUNCX parameter of the following form: FLO_FUNCX(reg,datayear,p,CG,'ACT') = shape index. Here, the CG should correspond to the group of commodities on the shadow side involved in the EQE_ACTEFF equation (the group, commodity type, or 'ACT' that was either explicitly or implicitly used in the ACT_EFF parameters that should be shaped).
Equation:

\[ EQE_{ACTEFF_{r,v,d,p,cg,ls}} \equiv (rtp_{vintyr_{r,v,d,p}} \land \neg rp_{inout_r,p,j0} \land ACT_{EFF_{r,v,p,cg,ls}}) \]

\[
\sum_{\text{com}_{\text{gman},eqe}rtp_{,}\text{var}_{t,pa}} \left( \frac{\text{VAR}_{FLO_{r,v,l,c,ls}} \times \left( \begin{array}{c} \text{ACT}_{EFF_{r,v,p,c,ls}} \\ 1 \end{array} \right)}{\begin{array}{c} \text{ACT}_{EFF_{r,v,p,c,ls}} \\ \text{VAR}_{FLO_{r,v,l,p,ls}} \end{array}} \times \begin{array}{c} \text{RTCS}_{TSFR_{r,d,c,s,ls}} \\ \text{RTCS}_{TSFR_{r,d,c,s,ls}} \end{array} \right) \]

\[ = \left( \begin{array}{c} \text{VAR}_{ACT_{r,v,l,p,ls}} \\ \text{VAR}_{FLO_{r,v,l,p,ls}} \end{array} \right) \times \left( \begin{array}{c} \text{RP}_{PGACT_{r,p}} \\ \text{RP}_{PGACT_{r,p}} \end{array} \right) \]

\[
\sum_{\text{rpc}_{pfc,pd_e}} \left( \frac{1}{\text{ACT}_{EFF_{r,v,p,cg,ls}} \times \begin{array}{c} \text{ACT}_{EFF_{r,v,p,c,ls}} \\ 1 \end{array}} \times 1 \right) \times \left( \begin{array}{c} \text{ACT}_{EFF_{r,v,p,c,ls}} \\ \text{ACT}_{EFF_{r,v,p,c,ls}} \end{array} \right) \times \text{RTCS}_{TSFR_{r,d,c,s,ls}} \]

\[ + \sum_{\text{prc}_{b,pg,pa}} \left( \frac{\text{VAR}_{ACT_{r,v,l,p,ls}} \times \text{ACT}_{LOSE_{r,v,p,FX'}} \times \text{RS}_{FR_{r,s,ls}}}{\text{VAR}_{ACT_{r,v,l,p,ls}} \times \text{ACT}_{LOSE_{r,v,p,FX'}} \times \text{RS}_{FR_{r,s,ls}}} \right) \]
6.3.4 Equation: EQ_ACTFLO

Indices: region (r), vintage year (v), milestone year (t), process (p), time slice (s)

Type: =

Related variables: VAR_ACT, VAR_FLO, VAR_IRE

Related equations: EQ_COMBAL, EQ_CAPACT, EQ_PTRANS

Purpose: This equation defines the VAR_ACT activity variable in terms of the “primary flows” of a process. The primary flows are defined by the user through the prc_actunt set attribute.

Remarks:
- The internal set rtp_vintyr ensures that (v,t) expressions are generated for the vintaged processes and (t,t) for the non-vintaged ones.
- The constraint defines the activity of a process. The activity of a process is limited in the equation EQ(l)_CAPACT by the available capacity.
- rtp_vara(r,t,p) controls the valid periods in which the process can operate.
- rp_aire(r,p) controls which sides of an import/export process should define activity.
- If the activity of a process is defined by a single flow, the flow variable is replaced by the activity variable in case that the reduction algorithm is activated. Then, in all equations where the flow occurs, the activity variable is used instead. In this case the equation EQ_ACTFLO is not generated.

Equation:

\[
EQ\_ACTFLO_{r,v,t,p} \equiv rtp\_vintyr_{r,v,t,p} \land prc\_ts_{r,p,s} \land rtp\_vara_{r,t,p}
\]

**IF NOT** rp_cire

\[
VAR\_ACT_{v,d} = \sum_{c \in \text{prc\_actunt}} \frac{VAR\_FLO_{r,v,t,p,c}}{PRC\_ACTFLO_{r,v,p,c}}
\]

**The process is not an inter-regional process**

**IF** rp_cire

\[
VAR\_ACT_{t,v} = \sum_{c \in \text{prc\_actunt}} \frac{\sum_{i \in \text{rp\_aire}} VAR\_IRE_{r,v,t,p,c,s,i}}{PRC\_ACTFLO_{r,v,p,c}}
\]

**The process is an inter-regional trade process.**
6.3.5  Equation: EQ_ACTPL

Indices: region (r), vintage year (v), period (t), process (p), time slice (s)

Type: =

Related variables: VAR_ACT, VAR_UPS

Related equations: EQE_ACTEFFF

Purpose: This equation defines the variable proportional to the efficiency loss under partial loads, if endogenous partial load efficiencies are modeled for a process, or a corresponding cost penalty under partial loads.

Remarks:
- Endogenous partial load efficiencies can only be modeled for processes that have their efficiency modeled by the ACT_EFF parameter.
- The input parameter ACT_LOSPL(r,y,p,'FX') defines the proportional increase in specific fuel consumption at the minimum operating level, when modeling partial load efficiencies endogenously (for process p, vintage y, region r).
- The input parameter ACT_LOSPL(r,y,p,'LO') defines the minimum operating level used for the partial load efficiency function; default value is taken from ACT_UPS(r,y,p, 'ANNUAL', 'FX'), but if neither is specified, is set to 0.1.
- The input parameter ACT_LOSPL(r,y,p,'UP') defines the fraction of the feasible load range above the minimum operating level, below which the efficiency losses are assumed to occur; default value = 0.6.
- It is recommended that the minimum operating level is defined by the ACT_MINLD(r,v,p) parameter, which is then used as the default value for ACT_LOSPL(r,y,p,'LO'). However, if desired, the minimum level to be assumed can also be defined by explicitly specifying ACT_LOSPL('LO').
- When the ACT_CSTPL input parameter is defined instead of (or as a supplement to) ACT_LOSPL, the cost coefficient is applied in the objective function directly to the VAR_UPS_r,v,t,p,s,'FX' variable as defined by the EQ_ACTPL equation.

Notation:
- \( AF_{MIN_{r,v,p,s} } \) minimum operating level of online capacity of process \( p \), vintage \( v \) in timeslice \( s \), as defined by ACT_MINLD (default) or ACT_LOSPL('LO');
- \( PL_{LDL_{p,v}} \) the load level below which partial load efficiency losses start to occur for process \( p \), vintage \( v \);
- \( SUP(s) \) is the set of timeslices above timeslice \( s \) in the timeslice tree, but including also \( s \) itself;
- \( UPS(p) \) is the set of timeslices with start-ups/shut-downs allowed for process \( p \).
Equations:

\[ EQ_{\text{ACTPL}}_{r,v,t,p,s} \rightarrow (\text{rtp\_vintyr}_{r,v,t,p} \land \text{prc\_ts}_{r,p,s} \land (\text{ACT\_LOSPL}_{r,v,p,FX} > 0)) \]

\[
\begin{align*}
\text{VAR\_UPS}_{r,v,t,p,s,FX} & \geq \left( \text{COEF\_CPT}_{r,v,t,p} \left( \text{VAR\_NCAP}_{r,v,p} - \sum_{t \in \text{SUP}(s) \cap \text{UPS}(p)} \text{VAR\_UPS}_{r,v,t,p,s,N} \right) \right) \\
& \times \left( \text{PL\_LDL}_{r,v,p} \cdot \text{PRC\_CAPACT}_{r,p} \cdot G\_YRFR_{s} - \text{VAR\_ACT}_{r,v,t,p,s} \right)
\end{align*}
\]

\[
\frac{\text{AF\_MIN}_{r,v,p,\text{ANNUAL}}}{\text{PL\_LDL}_{r,v,p} - \text{AF\_MIN}_{r,v,p,\text{ANNUAL}}}
\]
6.3.6 Equation: EQ_ACTRAMP

Indices: region (r), vintage year (v), period (t), process (p), time slice (s), bound (bd)

Type: =

Related variables: VAR_ACT, VAR_NCAP, VAR_UPS

Related equations: EQE_CAPLOAD

Purpose: This equation defines maximum ramp-up and ramp-down rates for a standard process. The maximum ramp-rates are specified with the input parameter ACT_UPS(r,v,p,s,'UP') and ACT_UPS(r,v,p,s,'LO'), as fractions of the nominal on-line capacity per hour.

Remarks:
- The amount of on-line capacity is the full available capacity, unless start-ups / shut-downs have been enabled by using the parameter ACT_MINLD.

Notation:
- SUP(s) is the set of timeslices above timeslice s in the timeslice tree, but including also s itself
- UPS(p) is the set of timeslices with start-ups/shut-downs allowed for process p.

Equations:

\[ EQ\_ACTRAMP_{r,v,t,p,s,UP} \equiv (rtp\_vintyr_{r,v,t,p} \land \text{prc\_ts}_{r,p,s} \land (ACT\_UPS_{r,v,p,UP} > 0)) \]
\[
\left( \frac{VAR\_ACT_{r,v,t,p,s}}{G\_YRFR_{r,s}} - \frac{VAR\_ACT_{r,v,t,p,s-1}}{G\_YRFR_{r,s}} \right) - \left( \frac{VAR\_UPS_{r,v,t,p,s,UP}}{G\_YRFR_{r,s}} - \frac{VAR\_UPS_{r,v,t,p,s,'LO'}}{G\_YRFR_{r,s}} \right) \cdot ACT\_UPS_{r,v,p,s,'FX'} \times 
\]
\[
2 \cdot RS\_STGPRD_{r,s} \cdot \frac{8760 \times (G\_YRFR_{r,s} + G\_YRFR_{r,s-1})}{VAR\_NCAP_{r,v,p} - \sum_{ts \in SUP(s) \land UPS(p)} VAR\_UPS_{r,v,t,p,s,N'}} \times 
COEF\_CPT_{r,v,t,p} \times PRC\_CAPACT_{r,p} \times ACT\_UPS_{r,v,p,s,UP} 
\]

\[ EQ\_ACTRAMP_{r,v,t,p,s,'LO'} \equiv (rtp\_vintyr_{r,v,t,p} \land \text{prc\_ts}_{r,p,s} \land (ACT\_UPS_{r,v,p,'LO'} > 0)) \]
\[
\left( \frac{VAR\_ACT_{r,v,t,p,s-1}}{G\_YRFR_{r,s-1}} - \frac{VAR\_ACT_{r,v,t,p,s}}{G\_YRFR_{r,s}} \right) - \left( \frac{VAR\_UPS_{r,v,t,p,s,'LO'}}{G\_YRFR_{r,s}} - \frac{VAR\_UPS_{r,v,t,p,s,UP}}{G\_YRFR_{r,s}} \right) \cdot ACT\_UPS_{r,v,p,s,'FX'} \times 
\]
\[
2 \cdot RS\_STGPRD_{r,s} \cdot \frac{8760 \times (G\_YRFR_{r,s} + G\_YRFR_{r,s-1})}{VAR\_NCAP_{r,v,p} - \sum_{ts \in SUP(s-1) \land UPS(p)} VAR\_UPS_{r,v,t,p,s,N'}} \times 
COEF\_CPT_{r,v,t,p} \times PRC\_CAPACT_{r,p} \times ACT\_UPS_{r,v,p,s,'LO'} 
\]
6.3.7 Equation: EQL_ACTUPC

Indices: region (r), vintage year (v), period (t), process (p), timeslice level (tsl), lim_type (l), time slice (s)

Type: \( \leq \)

Related variables: VAR_UPS, VAR_NCAP, VAR_RCAP

Related equations: EQE_ACTUPS, EQ_CAPLOAD

Purpose: This equation has two purposes, according to the lim_type (l):
1. It defines a lower limit for consecutive on-line / off-line hours of process capacity, such that capacity started-up cannot be immediately shut down again, or capacity shut-down cannot be immediately started up again. This purpose is served when lim_type=LO/UP.
2. It defines a maximum number of start-up cycles for the process capacity within the timeslice cycle under the parent timeslice.

Remarks:
- The minimum on-line / off-line hours are defined by using the input attribute \( ACT\_TIME_{r,v,p,bd} \), where bd = LO/UP. The maximum number of start-up cycles is defined by using the input attribute \( ACT\_TIME_{r,v,p,'N'} \).

Notation:
- \( SUP(s) \) is the set of timeslices above timeslice \( s \) in the timeslice tree, but including also \( s \) itself,
- \( UPS(p) \) is the set of timeslices with start-ups/shut-downs allowed for process \( p \),
- \( P(s) \) and \( C(s) \) refer to the parent timeslice of \( s \) and the set of child timeslices of \( s \), respectively.

Equations:

Case A: Lower limit for consecutive on-line / off-line hours

\[
EQ\_ACTUPC_{r,v,t,tsl,UP,s} \ni (rtp\_vintyr_{r,v,t} \wedge prc\_ts_{r,v,t} \wedge ts\_group_{r,tsl,s} \wedge (ACT\_TIME_{r,t,p,'UP'} > 0)) \\
\sum_{ts \in C(P(s))} VAR\_UPS_{r,v,t,ts,UP} \times (\text{mod}(\text{Hour}(s) - \text{Hour}(ts),24) < ACT\_TIME_{r,v,p,'UP'}) \leq \\
\left( VAR\_NCAP_{r,v,p} - \sum_{ts \in SUP(s) \setminus UPS(p)} VAR\_UPS_{r,v,t,ts,'N'} \right)
\]
\[ EQ\_\_ACTUPC_{r,v,t,p,ts,l,LO,s} \land (rtp\_vintyr_{r,v,t,p} \land prec\_ts_{r,p,s} \land ts\_group_{r,ts,l,s} \land (ACT\_TIME_{r,t,p;LO} > 0)) \]
\[ \sum_{ts \in C(p(s))} VAR\_UPS_{r,v,t,p,ts,l,LO} \times (\text{mod}(\text{Hour}(s) - \text{Hour}(ts), 24) < ACT\_TIME_{r,v,p;LO}) \leq (VAR\_UPS_{r,v,t,p,ts,s,N}) \]

Case B: Maximum number of start-up cycles within parent timeslice cycle

\[ EQ\_\_ACTUPC_{r,v,t,p,ts,l,N,s} \land (rtp\_vintyr_{r,v,t,p} \land \left( s \in \bigcup_{ts} \{P(ts) \mid prec\_ts_{r,p,ts}\} \right) \land ts\_group_{r,ts,l,s} \land (ACT\_UPS_{r,v,p;ANNUAL;N} > 0)) \]
\[ \sum_{ts \in C(s)} VAR\_UPS_{r,v,t,ts,UP} \leq \left( VAR\_NCAP_{r,v,p} - \sum_{ts \in SUP(s)} \sum_{UP(s)} VAR\_UPS_{r,v,t,ts,N} \right) \times ACT\_UPS_{r,v,p;ANNUAL;N} \]
6.3.8  Equation: EQE_ACTUPS

Indices: region (r), vintage (v), period (t), process (p), timeslice level (tsl), timeslice (s)

Type: =

Related variables: VAR_UPS

Related equations: EQL_ACTUPS, EQ_CAPLOAD

Purpose: This equation establishes the relation between start-ups/shut-downs and the change in the amount of on-line capacity between successive timeslices. It is generated only when start-up costs have been defined for a standard process with ACT_CSTUP.

Notation:
- \( UPS(r,p,tsl) \) is the set of timeslice levels with start-ups/shut-down costs defined for process p.

Equation:

\[
EQE_ACTUPS_{r,v,t,tsl,s} \equiv (rtp_vintyr_{r,v,t,p} \land UPS_{r,p,tsl}^+ \land ts\_group_{t,s,tsl})
\]

\[
VAR\_UPS_{r,v,t,p,s,up} - VAR\_UPS_{r,v,t,p,s,lo} = VAR\_UPS_{r,v,t,p,s-1,n} - VAR\_UPS_{r,v,t,p,s,n}
\]
6.3.9  Equation: EQL_ACTUPS

Indices: region (r), vintage year (v), period (t), process (p), timeslice level (tsl),
lim_type (l), time slice (s)

Type:  ≤

Related variables: VAR_UPS

Related equations: EQE_ACTUPS, EQ_CAPLOAD

Purpose: This equation ensures that startup costs are being consistently applied when start-
up costs have been defined on multiple timeslice levels.

Notation:
- UPS+ (r,p,tsl) is the set of timeslice levels with start-ups/shut-down costs defined
  for process p.
- P(r,s) refers to the parent timeslice of s in region r.

Equations:

Case A: lim_type='N'

\[
EQL\_ACTUPS_{r,v,t,p,tsl,N',s} \Rightarrow (rtp\_vintyr_{r,v,t,p} \land UPS^{+}_{r,p,tsl} \land ts\_group_{r,tsl,s})
\]

\[
VAR\_UPS_{r,v,t,p,s,N'} \leq VAR\_UPS_{p,v,t,P(s),FX'}
\]

Case B: lim_type='FX'

\[
EQL\_ACTUPS_{r,v,t,p,tsl,FX',s} \Rightarrow (rtp\_vintyr_{r,v,t,p} \land UPS^{+}_{r,p,tsl} \land
\left\{ ts\_group_{r,tsl,s} \land s \in \left( \bigcup_{sl} P(sl) \mid sl \in UPS^{+}(p) \right) \right\})
\]

\[
VAR\_UPS_{r,v,t,p,s,FX'} \leq \sum_{ts \in C(s)} VAR\_UPS_{r,v,t,p,ts,UP'}
\]
6.3.10 Equation: EQ(l)_ASHAR

Indices: region \((r)\), vintage year \((v)\), period \((t)\), process \((p)\), time slice \((s)\)

Type: As determined by the bd index of the input parameter FLO_SHAR:

- \(l = 'G'\) for \(bd = 'LO'\) yields \(\geq\),
- \(l = 'L'\) for \(bd = 'UP'\) yields \(\leq\),
- \(l = 'E'\) for \(bd = 'FX'\) yields \(=\).

Related variables: VAR_FLO, VAR_ACT, VAR_SOUT

Related equations: EQ(l)_INSHR, EQ(l)_OUTSHR

Purpose: A share equation between process flows/activity is generated a process \((p)\) in region \((r)\) for time period \((t)\) and each time-slice \((s)\). The equation is similar to the equations EQ(l)_INSHR and EQ(l)_OUTSHR, but is only generated when the input parameter \(FLO\_SHAR_{r,v,p,c,cg,s,bd}\) is specified in a non-standard way, for a commodity \(c\) and group \(cg\) such that \(c\) is not a member of group \(cg\), or such that \(c = cg\).

Remarks:

- Internally, the non-standard \(FLO\_SHARs\) are converted into the corresponding \(FLO\_ASHAR\) parameters.
- In general, the constraint is generated on the level of the process flow variable for \(c\), unless \(c = 'ACT'\), which will result in an annual level constraint.
- When \(c = 'ACT'\), the equation defines a bound on the amount of activity in proportion to the flows in the group \(cg\), on the ANNUAL level.
- When \(cg = 'ACT'\), the equation defines a bound on the amount of flow of \(c\) in proportion to the activity, on the level of the process flow variable for \(c\).
- When \(c = cg\), and \(c\) is a member of the default shadow group, the share equation is generated for the flow of \(c\) in the total flow of commodities in the SPG, and either on the group level or on the WEEKLY level, whichever is higher. This feature makes it easy to define e.g. daily share constraints for a DYNAMITE level process, such as fuel shares for plug-in hybrid cars.
- When the process is a storage process, the only valid share specification is \(FLO\_SHAR_{r,v,p,c,ACT,s,bd}\), where \(c\) is the discharge commodity of a timeslice storage. This generates a constraint between the output flow and the storage activity, which can be useful e.g. for preventing the use of the storage for a by-pass operation. The \(cg\) is set automatically to the SPG when the \(FLO\_SHAR\) is converted into \(FLO\_ASHAR\).
\[ EQ(l) \_ ASHAR_{r,v,t,p,c,g,s,t} = \left( rtp\_vintyr_{r,v,t,p} \land \left( rpcs\_var_{r,p,c,s} \lor \left( \left( c = 'ACT' \right) \land \text{annual}_{s,t} \right) \right) \right) \land \sum_{ts\_map_{s,t}} FLO \_ ASHAR_{r,v,p,c,g,t}\_s,bd_t \]

**Case A:** Standard processes:

\[
\sum_{rps\_s,t} FLO \_ ASHAR_{r,v,p,c,g,s,sl,bd} \times RS \_ FR_{r,s,sl} \times \left( \sum_{come_{cg}} \sum_{rtcps\_var_{r,t,p,com,ts}} \sum_{RPC\_ACTFLO_{r,v,com}} \frac{VAR \_ FLO_{r,v,t,p,com,ts}}{PRC\_ACTFLO_{r,v,com}} \times RTCS \_ TSFR_{r,t,p,com,sl,ts} \right) \left( \sum_{come_{[c='ACT']}} \sum_{prc\_br_{r,p,ts}} \frac{VAR \_ FLO_{r,v,t,p,com,ts}}{PRC\_ACTFLO_{r,v,com}} \times RTCS \_ TSFR_{r,t,p,com,sl,ts} \right) \}
\]

**Case B:** Storage processes:

\[
\sum_{rps\_s,t} FLO \_ ASHAR_{r,v,p,c,'ACT',sl,bd} \times RS \_ FR_{r,s,sl} \times \left( \sum_{come_{[c='ACT']}} \sum_{prc\_pg_{r,p,com}} \sum_{prc\_br_{r,p,ts}} \frac{VAR \_ FLO_{r,v,t,p,com,ts}}{PRC\_ACTFLO_{r,v,com}} \times RTCS \_ TSFR_{r,t,p,com,sl,ts} \right) \}
\]

\[
\sum_{rtcps\_var_{r,t,p,com,ts}} \frac{VAR \_ SOUT_{r,v,t,p,com,ts}}{PRC\_ACTFLO_{r,v,com}} \times RTCS \_ TSFR_{r,t,p,com,sl,ts} \]

192
6.3.11 Equation: EQ(\(l\))_{BLND}

Indices: region \((r)\), year \((t)\), refinery product \((ble)\), specification \((spe)\)

Type: Any type, as determined by the value of the input parameter BL\_TYPE\((r,ble,spe)\):
- \(l = 'L'\) for a value of 1 yields \(\leq\).
- \(l = 'G'\) for a value of 2 yields \(\geq\).
- \(l = 'E'\) for a value of 3 yields \(=\).

Related variables: VAR\_BLND

Related equations: EQ\_COMBAL

Purpose: The blending equations ensure that the characteristics of petroleum products (e.g. sulfur content, density, octane number, etc.) lie within specified limits, if desired.

Remarks:
- Parameter BL\_COM contains the values of the blending specifications \(spe\) for the blending streams \(opr\).
- Parameter BL\_SPEC contains the value of the specification \(spe\) of the blending product \(ble\).
- The blending variables VAR\_BLND are expressed in volume units. If the characteristics of the blending streams \(opr\) and the product \(ble\) are not given in volume units (indicated by input parameter REFUNIT), the user has to provide a conversion parameter CONVERT which contains the density and energy content (by weight or by volume) of each blending stream. The conversion parameters are used to derive the coefficients RU\_CVT of the blending streams in the blending equation.

Equation:

\[
EQ(l)_{BLND} \quad \exists \ bl \_type_{r,ble,spe} \\
\sum_{oprbleoptr} BL\_COM_{r,ble,opr,spec} \cdot RU\_CVT_{r,ble,opr,spe} \cdot VAR\_BLND_{r,ble,opr} \cdot \{\leq;=;\geq\} \\
\sum_{oprbleoptr} BL\_SPEC_{r,ble,opr,spec} \cdot RU\_CVT_{r,ble,opr,spe} \cdot VAR\_BLND_{r,ble,opr}
\]
6.3.12 Equation: EQ_BNDCST

Indices: region (r), year1 (y1), period (t), year2 (y2), cost aggregation (costagg), currency (cur)

Type: =

Related variables: VAR_CUMCST

Related equations: EQ_OBJ

Purpose: This equation is generated when a bound is specified on regional costs, taxes and/or subsidies, either cumulative over a year range (using REG_CUMCST_r,y1,y2,agg,cur,bd) or in given milestone years (using REG_BNDCST_r,y,agg,cur,bd). It sets the level of the variable VAR_CUMCST_r,y1,y2,costagg,cur equal to the cost expression, to be bounded accordingly.

Remarks:
- The available cost aggregations that can be bounded are listed in the table below.
- All the cost components related to investments are expressed in terms of annualized capital costs, i.e. as annuities paid in the year(s) in question. These components thus include interest during both construction and payback time.
- In all combined cost aggregations, subsidies are treated as negative costs when summed up with other cost/taxes, but when bounded alone they are treated as positive.

&\sum_{y=1}^{y_2} \text{FLOTAX}(r,y) \times (\text{cost}_{\text{agg},\text{FLOTAX}}) \\
&\sum_{y=1}^{y_2} \text{FLOSUB}(r,y) \times (\text{cost}_{\text{agg},\text{FLOSUB}})
\end{align*}
\]
6.3.13 Equation: EQ(l)_BNDNET/PRD

Indices: region (r), period (t), commodity (c), timeslice (s)

Type: Any type, as determined by the bound index \(bd\) of COM_BNDNET/PRD:
- \(l = 'G'\) for \(bd = 'LO'\) (lower bound) yields \(\geq\).
- \(l = 'E'\) for \(bd = 'FX'\) (fixed bound) yields \(=\).
- \(l = 'L'\) for \(bd = 'UP'\) (upper bound) yields \(\leq\).

Purpose: If the bound on the net or gross production of a commodity is specified for a timeslice being above the timeslice level of the commodity, the equation described here is generated. The bound on the net or gross production of a commodity is directly applied to the variable (VAR_COMNET, VAR_COMPRD), if the bound parameter is specified for a commodity timeslice (com_ts).

Remarks:
- The internal set \(rcs\_comts\) used in the equation contains all timeslices at or above the timeslice level being defined for the commodity.
- The internal set \(rtcs\_varc\) used in the summation part of the equation contains all timeslices (out of \(com\_ts\)) and periods for which the commodity is available.
- The internal set \(ts\_map(r,s,ts)\) used in the summation part of the equation contains for a given timeslice (s) all timeslices (ts) being at or below s in the timeslice tree.

Interpretation of the results:
Primal: Value of the net production of a commodity (production minus consumption)
Dual: marginal cost of increasing the bound by one unit

Equation

\[
EQ(l)_BNDNET/PRD_{r,t,c,s} \\
\exists \{rcs\_comts_{r,c,s} \land \lnot com\_ts_{r,c,s} \land COM\_BND(NET/PRD)_{r,t,c,s,\text{x}} \} \\
\sum_{rcs\_varc_{r,c,s},ts\_map_{r,c,s}} \text{VAR\_COM}(NET/PRD)_{r,t,c,ts} \\
(\leq/\geq/=)
\]

\(COM\_BND(NET/PRD)_{r,t,c,s,\text{x}}\)

Sign according to the \(l\) equation index (must coincide with the \(bd\) index in parameter COM_BNDNET/PRD).
6.3.14 Equation: EQ(l)_CAFLAC

Indices: region (r), vintage year (v), period (t), process (p), time slice (s)

Type: As determined by the bd index of the standard availability parameter:
- \( l = 'L' \) for \( bd = 'UP' \) yields \( \leq \),
- \( l = 'E' \) for \( bd = 'FX' \) yields \( = \).

Related variables: VAR_NCAP, VAR_FLO, VAR_IRE, VAR_SIN, VAR_SOUT

Related equations: EQ(l)_CAPACT, EQL_CAPFLO

Purpose: This equation relates the flows in the primary group of a process to its available existing capacity in period \( t \). The existing capacity consists of investments made in the current and previous periods (VAR_NCAP) and investment decisions that have been made exogenously \((NCAP_PAST/PRC_RESID)\). The availability of the existing capacity in a specific period \( t \) and timeslice \( s \) can be specified by the input attribute \( NCAP_AFC_{r,v,p,cg,tsl} / NCAP_AFCS_{r,v,p,cg,s} \), where \( cg \) can be a single commodity in the PG, thereby making the process availability factor dependent on the output mix.

Remarks:
- The \( cg \) index in the input attributes \( NCAP_AFC_{r,v,p,cg,tsl} \) specified overrides an \( NCAP_AFC_{r,v,p,cg,tsl} \) specified on the same level, and any value specified for a single commodity overrides a value specified for a group containing the commodity.
- For storage and trade processes, which both can have the same commodity IN and OUT of the process, defining an \( NCAP_AFC/NCAP_AFCS \) both for the commodity type and for the single commodity itself results in the commodity availability being applied to the output flow while the group availability is applied to the input flow.
- For storage processes, defining an \( NCAP_AFC/NCAP_AFCS \) on the reserved group name 'ACT' defines a separate availability factor constraint \((EQL_CAPFLO)\) for the storage level, and not for the flows in the PG.
- For trade processes, \( prc_map_{r,'DISTR',p} \) can be also used for removing exports from contributing to the availability equation, if the process is bi-directional.

Special notation used for the equation formulation:
- \( SX_{r,v,p,c,s} \) denotes an adjustment coefficient for storage inputs:

\[
SX_{r,v,p,c,s} = \begin{cases} 
0 & \text{if} \top_{\text{OUT}}(c) \wedge \top_{\text{IN}}(c) \wedge \neg NCAP_{-AFCS_{r,v,p,cg,s}} \\
\frac{NCAP_{-AFCS_{r,v,p,c,cg,s}}}{\sum_{rp\in P_{rp}} NCAP_{-AFCS_{r,v,p,c,g,s}}} & \text{if} \top_{\text{OUT}}(c) \wedge \top_{\text{IN}}(c) \wedge \neg NCAP_{-AFCS_{r,v,p,cg,s}} \\
1 & \text{otherwise} 
\end{cases}
\]
\[ IX_{r,v,p,c,s} \text{ denotes an adjustment coefficient for trade process exports:} \]

\[
IX_{r,v,p,c,s} = \begin{cases} 
\frac{NCAP\_AFCS_{r,v,p,c,s}}{\sum_{rp,pg,eq} NCAP\_AFCS_{r,v,p,eq,s}} & \text{if } imp(c) \land exp(c) \land \\
1 & \text{otherwise} 
\end{cases} 
\]

Equation:

\[
EQ(l)\_CAFLAC_{r,v,l,p,t} \Rightarrow \left( \begin{array}{c} 
rtp\_vintyr_{r,v,l,p} \land NCAP\_AFCS_{r,v,p,s} \\
\left( NCAP\_AF_{r,v,p,bd} \lor NCAP\_AFS_{r,v,p,bd} \lor NCAP\_AFA_{r,v,p,bd} \right) 
\end{array} \right) 
\]

\[
\frac{1}{PRC\_ACTFLO_{r,v,p,c}} \times \left( 
\begin{array}{c} 
1/NCAP\_AFCS_{r,v,p,c,s} & \text{if } NCAP\_AFCS_{r,v,p,c,s} \text{ given} \\
\sum_{rp,pg,eq} \frac{1}{NCAP\_AFCS_{r,v,p,eq,s}} & \text{elseif } NCAP\_AFCS_{r,v,p,eq,s} \text{ given} \\
1 & \text{otherwise} 
\end{array} \right) 
\]

\[
\sum_{rp,pg,eq,prc_{r,v,p}} \left( \begin{array}{c} 
VAR\_FLO_{r,v,l,p,c,s} & \text{if } rp\_std_{r,p} \\
\left( VAR\_SOUT_{r,v,l,p,c,s} + VAR\_SIN_{r,v,l,p,c,s} \times SX_{r,v,p,c,l,t} \right) & \text{if } rp\_stg_{r,p} \\
\left( VAR\_IRE_{r,v,l,p,c,s,mp} + VAR\_IRE_{r,v,l,p,c,s,mp} \times \exp' \times IX_{r,v,p,c,s} \right) & \text{if } rp\_ire_{r,p} \\
\times RTCS\_TSFR_{r,t,c,s,l,t} & 
\end{array} \right) 
\]

\[
\sum_{i=1}^{2} \left( \begin{array}{c} 
COEF\_AF_{r,v,l,p,s} \times COEF\_CPT_{r,v,l,p} \times \\
\left( VAR\_NCAP_{r,v,p} + NCAP\_PASTI_{r,v,p} - \\
\left( VAR\_SCAP_{r,v,l,p} \text{ if } PRC\_RCAP_{r,p} \right) \right) \\
\times PRC\_CAPACT_{r,p} & \text{if } -prc\_vint_{r,p} \\
\end{array} \right) 
\]

\[
+ \left( \begin{array}{c} 
COEF\_AF_{r,v,l,p,s} \times COEF\_CPT_{r,v,l,p} \times \\
\left( VAR\_NCAP_{r,v,p} + NCAP\_PASTI_{r,v,p} - \\
\left( VAR\_SCAP_{r,v,l,p} \text{ if } PRC\_RCAP_{r,p} \right) \right) \\
\times PRC\_CAPACT_{r,p} & \text{if } prc\_vint_{r,p} \\
\end{array} \right) 
\]
6.3.15 Equation: EQ(l)_CAPACT

Indices: region (r), vintage year (v), period (t), process (p), time slice (s)

Type: Determined by the bound index bd of NCAP_AF, NCAP_AFS or NCAP_AFA:
- \( l = 'E' \) for bd = ‘FX’ (fixed bound) yields = .
- \( l = 'L' \) for bd = ‘UP’ (upper bound) yields ≤.
- \( l = 'G' \) for bd = ‘LO’ (lower bound) yields ≥.

Related variables: VAR_ACT, VAR_NCAP, VAR_FLO

Related equations: EQ_ACTFLO, EQ_COMBAL, EQ_INSHR, EQ_OUTSHR, EQ_PTRANS

Purpose: The capacity-activity equation relates the activity of a process to its available existing capacity in period t. The existing capacity consists of investments made in the current and previous periods (VAR_NCAP) and investment decisions that have been made exogenously (NCAP_PAST/PRC_RESID). The availability of the existing capacity in a specific period t and timeslice s is specified by the availability factor. Three availability factors exist:
- NCAP_AF(r,v,p,s,bd):
  Availability factor specified for a specific period and timeslice. If this availability factor is not specified for the process timeslices (prc_ts), the availabilities are aggregated/inherited according to the timeslice tree. Thus, for a process operating on the DAYNITE level it is sufficient to specify only one availability for the ANNUAL timeslice, which is then inherited to the DAYNITE timeslices.
- NCAP_AFS(r,v,p,s,bd):
  Availability factor specified for a specific period and timeslice. In contrast to NCAP_AF, this availability is not inherited/aggregated along the timeslice tree. If this availability is specified for a seasonal timeslice for a process operating on the DAYNITE level, the capacity-activity constraint is generated for the seasonal timeslice and sums over the DAYNITE activities. This gives the process flexibility how to operate within the seasonal timeslice as long as the overall seasonal availability restriction is fulfilled.
- NCAP_AFA(r,v,p,bd):
  Annual availability factor similar to NCAP_AFS being specified for the ANNUAL timeslice with the difference that NCAP_AFA is always applied in such a way as if the process is non-vintage dependent, even if it is specified as a vintaged one (prc_vint). Thus the annual availability factor is especially useful to calibrate the activity of a process in the first period(s) to the statistics irrespectively of its vintage structure and the vintage dependent activities (NCAP_AFS), which can be specified in addition to NCAP_AFA.

If the process is defined as a vintaged one (prc_vint), for each vintage year (v) of the existing capacity stock in period (t) a separate capacity-activity constraint will be generated
(exception NCAP_AFA), while for a non-vintaged process one capacity-activity constraint is generated that sums over all vintage years. In the latter case the vintage index of the equation (EQ(l)_CAPACT(r,v,t,p,s)) always equals the period index (v = t).

Remarks:

- For all process timeslices (prc_ts), NCAP_AF(r,t,p,s,’UP’) is by default set to 1, unless NCAP_AF(‘UP’) or NCAP_AF(‘FX’) has been specified by the user. Thus, it is ensured that the activity of a process can never exceed its capacity. If for example only NCAP_AFA is specified by the modeler as annual availability for a process with a DAYNITE timeslice resolution, in addition to the annual activity-capacity constraint activity-capacity constraints with an availability of 100% are generated for the DAYNITE process timeslices.

- An average value of the availability factors (NCAP_AF/S) over the years in the period is used when an age-dependent ‘Shape’ is specified for them.

- rtp_cptyr identifies the capacities installed in period v still available in period t. This set takes into account that investments may be turned-off for certain periods (by PRC_NOFF). The condition is as under:

  \[
  v, t \text{ such that } \\
  B(v) \geq B(t) - (\text{COEF\_RPTI}\times\text{T LIFE}) - \text{ILED} + 1 \\
  \text{and} \\
  B(v) \leq E(t) - \text{ILED}
  \]

- prc_vint is a set of processes for which attributes are changing over time and vintaging is required.

- Entries in rtp_vintyr are controlled by the same logic as applied to COEF_CPT combined with the vintaging consideration. Note v = t when no vintaging is required, or vintaging is turned off for a particular processes, where the sum over the previous investments is used instead of individual variables.

- COEF_AF(r,v,t,p,s,bd) will be read off a pre-processed table, after application of SHAPE and MULTI to the user provided availabilities (NCAP_AF/A/S).

- COEF_AF is calculated in the following manner:
  1) aggregate if possible (pp_lvlbd.mod), otherwise inherit (in ppmain.mod)
  2) apply SHAPE and MULTI to NCAP_AF/S

- For storage processes, the capacity describes the volume of the storage and the activity the storage content. For storage processes between timeslices (prc_tgtss, prc_nstts) parameter RS_STGPRD is used instead of G_YRFR. RS_STGPRD(r,s) equals the number of storage periods on the timeslice level of timeslice s in the whole year multiplied with the duration of its parent timeslice ts. Thus, the storage level VAR_ACT (and indirectly the storage in- and output flows VAR_SIN and VAR_SOUT) are scaled-up for the entire year.

  Consequently, the value of RS_STGPRD(r,s) is:
  - 1 for a seasonal storage,
  - 365/7*G_YRFR(r,ts) for a weekly storage, where ts is the parent node of s,
  - 365*G_YRFR(r,ts) for a daynite storage, where ts is the parent node of s.
Interpretation of the results:

Primal: In case of an inequality constraint and no past investments (i.e. RHS is zero), the primal value describes the difference between the activity level and the maximum possible activity due to the installed capacity in the considered period and timeslice. If the primal value is negative, it means that the capacity is not fully utilized. In case of past investments, the RHS is not zero\(^{42}\), but has a positive value and corresponds to the possible activity due to the past investments. If the primal value equals the RHS value, the capacity is fully utilized. If not the difference (RHS minus primal value), where the primal value may also be negative, describes the possible unused activity production.

Dual: The dual value is in case of an inequality constraint a negative number, when the constraint is binding. It describes the cost reduction caused by an additional capacity unit and can thus be interpreted as the value of the capacity. For a power plant for example it can be viewed as the part of the electricity price that can be used for covering the fixed operating and investment costs of the capacity (multiplied by the corresponding coefficient in the dual equation of the electricity flow variable). If NCAP_AFS or NCAP_AFA are applied for timeslices above the process timeslice level, in addition capacity-activity constraints (with a default value for NCAP_AF of 1 as upper bound) are generated for the process timeslices. The dual value of the constraints related to NCAP_AFS or NCAP_AFA serve as benchmark value of the capacity between the process timeslices. If for example NCAP_AFA is given for a power plant with a DANYITE timeslice resolution (e.g. WD, WN, SD, SN), the NCAP_AF related capacity constraints with an availability of 1 are usually binding only in one process timeslice level, e.g. WD. Now the dual variable of NCAP_AFA can be seen as rent that must be covered in other process timeslices (WN, SD, SN) by the then prevailing electricity price, so that the model would decide to shift the scarce annual capacity from WD to another timeslice.

\(^{42}\) GAMS moves all constants (e.g. past investments) on the RHS and the variables on the LHS of the equation. In the listing file the primal value of the equation can be found in the solution report under the LEVEL column. The RHS value is given under the column UPPER column in case of a \(\leq\) inequality and in the LOWER column for a \(\geq\) inequality. For an equality LOWER, LEVEL and UPPER value are the same.
Equation:

$$EQ(l)_\text{CAPACT}_{r,v,t,p} \equiv \text{rtp_vintyr}_{r,v,t,p} \land \text{pre_ts}_{r,p,s} \land \text{rtp_vara}_{r,t,p} \land \left( \text{NCAP}_\text{AF}_{r,t,p,s} \lor \text{NCAP}_\text{AFS}_{r,t,p,s} \lor \text{NCAP}_\text{AFA}_{r,t,p} \right)$$

$$\begin{cases}
\sum_{t \in \text{pre_ts}_{r,p,s} \cap \text{ts_map}_{p,i}} \text{VAR}_\text{ACT}_{r,v,t,p,s} & \text{if } -\text{pre_map}_{r,\text{STG}p} \\
\sum_{t \in \text{pre_ts}_{r,p,s}} \frac{\text{VAR}_\text{ACT}_{r,v,t,p,s}}{\text{RS}_\text{STGPRD}_{r,t}} \times \text{RS}_\text{FR}_{r,t,s} & \text{if } \text{pre_map}_{r,\text{STG}p}
\end{cases} \quad \{\leq;=;\geq\}$$

Case1: Non-vintaged process ($v = t$):

$$\sum_{v \neq \text{rtp_cpyr}_{r,t,p}} \left( \text{COEF}_\text{AF}_{r,v,t,p,s,bd} \times \text{COEF}_\text{CPT}_{r,v,t,p} \times \left( \text{VAR}_\text{NCAP}_{r,v,t,p} + \text{NCAP}_\text{PASTI}_{r,v,t,p} - \left( \text{VAR}_\text{SCAP}_{r,v,t,p} \text{ if } \text{PRC}_\text{RCAP}_{r,p} \right) \right) \times \text{PRC}_\text{CAPACT}_{r,p} \right) \quad \text{if } -\text{pre_vint}_{r,p}$$

Case2: Vintaged process ($v = \text{vintage}$):

$$\sum_{v = \text{rtp_cpyr}_{r,t,p}} \left( \text{COEF}_\text{AF}_{r,v,t,p,s,bd} \times \text{COEF}_\text{CPT}_{r,v,t,p} \times \left( \text{VAR}_\text{NCAP}_{r,v,t,p} + \text{NCAP}_\text{PASTI}_{r,v,t,p} - \left( \text{VAR}_\text{SCAP}_{r,v,t,p} \text{ if } \text{PRC}_\text{RCAP}_{r,p} \right) \right) \times \text{PRC}_\text{CAPACT}_{r,p} \right) \quad \text{if } \text{pre_vint}_{r,p}$$

$$\times \left[ G_\text{YRFR}_{r,s} \times (p \notin \text{pre_map}_{r,\text{STG}p}) + 1 \times (p \in \text{pre_map}_{r,\text{STG}p}) \right]$$
\( \text{COEF \_CPT}_{r,v,p} : \)

\[
\text{if } \quad v = t \\
\quad = \max \left( \frac{D(t) - \text{NCAP \_ILED}}{D(t)} \right) \quad \text{If } v \text{ has been a long time period, and } t \text{ is close enough to encounter a capacity created at the end of } v. \\
\text{else} \\
\text{if } \quad t \geq v \land D(v) > \text{IL} + \text{TL} \land B(t) < E(v) + \text{TL} \\
\quad = \max \left( \frac{\min\left(B(v) + \text{IL} + \text{COEF \_RPTI}_{r,v,p} \times \text{TL}, E(t) + 1\right) - B(t)}{D(t)} \right) \quad \text{Number of years of existence within period } t, \text{ divided by the period duration} \\
\text{else} \\
\quad = \max \left( \frac{\min\left(B(v) + \text{IL} + \text{TL}, E(t) + 1\right) - \max\left(B(v) + \text{IL}, B(t)\right)}{D(t)} \right) \quad \text{This step blocks out the investments that have already retired, which may be evaluated with a negative remaining life} \\
\text{endif} \\
\text{endif} \\

\( D(t) = \text{Duration of the period containing } t \)
6.3.16 Equation: EQL_CAPFLO

Indices: region (r), vintage (v), period (t), process (p), commodity (c), time slice (s)

Type: ≤

Related variables: VAR_NCAP, VAR_SCAP, VAR_FLO, VAR_ACT, VAR_UPS

Related equations: EQ(l)_CAFLAC

Purpose: The equation defines a maximum level for a process flow (standard processes) or activity (only for storage processes) in relation to its capacity, according to an NCAP_AFC/NCAP_AFCS parameter specified by the user.

Remarks:
- The equation is generated only for process flows not in the PG, as the PG flows are handled by EQ_CAFLAC. However, independent EQL_CAPFLO constraints may be requested also for the PG flows by setting NCAP_AFC_{r, v, p, 'ACT', ts} = 1.
- When defined for storage activity, note that the capacity is assumed to represent an annual production capacity equivalent to the amount produced by full power during one full year/week/day for SEASON/WEEKLY/DAYNITE level storage processes, respectively. The availability factor should be adjusted to correspond to the actual storage capacity. For example, a capacity of 1 GW is equal to 24 GWh for a DAYNITE storage, and if the real daily storage capacity is, say 8 GWh / GW, the maximum availability factor should be 0.333.
- The equation formulation is shown below is for the vintaged case only; the non-vintaged case differs in the RHS in the same way as in EQ(l)_CAPACT.

Notation:
- \( P(s) \) denotes the parent timeslice of \( s \).

Equation (vintaged case only):

\[
EQL\_CAPFLO_{r,v,t,p,c,s} \equiv \left( \bigwedge_{r,v,t,p,c,s} \left( \bigwedge_{r,v,t,p,c,s} \left( \bigwedge_{r,v,t,p,c,s} \left( \bigwedge_{r,v,t,p,c,s} \left( \bigwedge_{r,v,t,p,c,s} \left( \bigwedge_{r,v,t,p,c,s} \right) \right) \right) \right) \right) \)
\]

\[
\left( \sum_{r,v,t,p,c,s} \frac{VAR\_FLO_{r,v,t,p,c,s} \times NCAP\_AFC_{r,v,t,p,c,s}}{NCAP\_AFC_{r,v,t,p,c,s} \times \sum_{r,v,t,p,c,s} \left( \sum_{r,v,t,p,c,s} \right)} \right) \leq \left( \sum_{r,v,t,p,c,s} \left( \sum_{r,v,t,p,c,s} \left( \sum_{r,v,t,p,c,s} \left( \sum_{r,v,t,p,c,s} \left( \sum_{r,v,t,p,c,s} \right) \right) \right) \right) \right)
\]

\[
NCAP\_AFC_{r,v,t,p,c,s} \times \left( \sum_{r,v,t,p,c,s} \left( \sum_{r,v,t,p,c,s} \left( \sum_{r,v,t,p,c,s} \left( \sum_{r,v,t,p,c,s} \left( \sum_{r,v,t,p,c,s} \right) \right) \right) \right) \right)
\]

\[
COEF\_CPT_{r,v,t,p} \times PRC\_CAPACT_{r,p} \times G\_YRFR_{r,s}
\]
6.3.17 Equation: EQ_CAPLOAD

Indices: region (r), vintage year (v), period (t), process (p), time slice (s), lim_type (l)

Type: \leq

Related variables: VAR_ACT, VAR_NCAP, VAR_UPS

Related equations: EQE_ACTUPS

Purpose: This equation is used as a replacement for the standard EQ(l)_CAPACT equations for the process timeslices, whenever flexible minimum operating limits are defined for a standard process. It defines the maximum and minimum levels of activity in relation to the available capacity, taking also into account capacity that may have been shut-down during some timeslices. The difference to the standard EQ(l)_CAPACT equations is thus that EQ_CAPLOAD refers to the on-line capacity in each timeslice, while EQ(l)_CAPACT refers to the full available capacity.

Remarks:
- The flexible minimum operating limits are defined with the parameter ACT_MINLD(r,y,p). Any fixed lower bound availability factor at the process timeslice level is ignored when ACT_MINLD is defined.
- Star-ups/shut-downs of capacity are by default only allowed on the SEASON level, and without costs. More general dispatchability features can be activated by defining start-up costs, with the parameter ACT_CSTUP. Start-up costs can be optionally defined even on the SEASON level, if desired (see the Table below).
- Start-ups and shut-downs will always occur in pairs, and therefore any shut-down costs can be directly included in the ACT_CSTUP parameter. If start-ups on some level can be assumed without additional costs, it is advisable to leave ACT_CSTUP unspecified at that level. If the start-up costs are assumed zero on some timeslice level, they must be zero also on any higher levels.

\(S = \) start-ups enabled without cost
\(SC = \) start-ups enabled with costs
Notation:
- \( AF_{\text{MAX}}_{r,v,p,t,s} \) maximum operating level of online capacity of process \( p \), vintage \( v \), in period \( t \) and timeslice \( s \), as defined by NCAP_AF\('UP')
- \( AF_{\text{MIN}}_{r,v,p,s} \) minimum operating level of online capacity of process \( p \), vintage \( v \) in timeslice \( s \), as defined by ACT_MINLD
- \( SUP(s) \) is the set of timeslices above timeslice \( s \) in the timeslice tree, but including also \( s \) itself
- \( UPS(p) \) is the set of timeslices with start-ups/shut-downs allowed for process \( p \);

Note: Only vintaged case shown below, see the RHS of EQ_CAPACITY for the differences in the non-vintaged case.

Equations:

\[
EQ_{\text{CAPLOAD}}_{r,v,t,p,s,\text{UP}} \triangleright (rtp\_\text{vintyr}_{r,v,t,p} \land \text{prc\_ts}_{r,p,s} \land (ACT\_UPS_{r,v,p,s}; TF; > 0))
\]

\[
VAR\_ACT_{r,v,t,p,s} \leq AF\_\text{MAX}_{r,v,t,p,s} \times \left( \frac{VAR\_\text{NCAP}_{r,v(t,v),p} + NCAP\_\text{PASTI}_{r,v,p} - \sum_{prc\_rcap\_p} VAR\_\text{SCAP}_{r,v,t,p} - \sum_{utesUP\(s')\_UPS(p)} VAR\_\text{UPS}_{r,v,t,p,s'; N'}}{COEF\_\text{CPT}_{r,v,t,p} \cdot PRC\_\text{CAPACITY}_{r,p} \cdot G\_\text{YRFR}_{r,s}} \right)
\]

\[
EQ_{\text{CAPLOAD}}_{r,v,t,p,s,\text{LO}} \triangleright (rtp\_\text{vintyr}_{r,v,t,p} \land \text{prc\_ts}_{r,p,s} \land (ACT\_UPS_{r,v,p,s}; TF; > 0))
\]

\[
VAR\_ACT_{r,v,t,p,s} \geq AF\_\text{MIN}_{r,v,t,p,s} \times \left( \frac{VAR\_\text{NCAP}_{r,v(t,v),p} - NCAP\_\text{PASTI}_{r,v,p} - \sum_{prc\_rcap\_p} VAR\_\text{SCAP}_{r,v,t,p} - \sum_{utesUP\(s')\_UPS(p)} VAR\_\text{UPS}_{r,v,t,p,s'; N'}}{COEF\_\text{CPT}_{r,v,t,p} \cdot PRC\_\text{CAPACITY}_{r,p} \cdot G\_\text{YRFR}_{r,s}} \right)
\]
6.3.18 Equation: EQ(l)_CPT

Indices: region (r), period (t), process (p)

Type: Any type, as determined either by the bound index bd of CAP_BND or the need to have a capacity variable (learning technology or capacity variable used in user constraint):
- \( l = 'G' \) for \( bd = 'LO' \) (lower bound) yields \( \geq \), if no upper bound at the same time
- \( l = 'E' \) for \( bd = 'FX' \) (fixed bound), or for lower and upper capacity bound at the same time, or for learning technology or for capacity variable used in user constraint yields \( = \).
- \( l = 'L' \) for \( bd = 'UP' \) (upper bound) yields \( \leq \), if no lower bound at the same time.

Related variables: VAR_NCAP, VAR_CAP

Related equations: EQ(l)_CAPACT

Purpose: This equation adds up the investments (VAR_NCAP), which have been made in the current and previous periods and still exist in the current period, and past investments being made before the beginning of the model horizon and either assigns it to the capacity variable VAR_CAP or applies directly lower or upper capacity bounds to it.

Remarks:
- It is generated only for those milestone year & process combinations that have a corresponding CAP_BND specification, for processes where there is a user constraint involving a capacity variable, and for processes being a learning technology (teg).
- In case that only a lower or an upper capacity bound is specified, the capacity bounds are directly used as RHS constants. In the other cases, the capacity variable is used instead.
- The set \( rtp\_varp(r,t,p) \) describes the cases where a capacity variable is needed:
  - Capacity variable is used in a user constraint,
  - Lower and upper capacity bound are specified for the same period. In this case it is more efficient to generate one capacity variable by one EQE_CPT equation and bound the variable instead of generating the two equations EQL_CPT and EQG_CPT.
Equation:

\[ EQ(l) \_ CPT_{r,t,p} \supset CAP \_ BND_{r,t,p,bd} \lor \text{teg}_p \lor \text{rtp} \_ \text{varp}_{r,t,p} \]

\[ \text{VAR} \_ \text{CAP}_{r,t,p} \times (\text{rtp} \_ \text{varp}_{r,t,p} \lor \text{CAP} \_ \text{BND}_{r,t,p,FX} \lor \text{teg}_p) \]
\[ + \text{CAP} \_ \text{BND}_{r,t,p,LO'} \times (\text{NOT} \text{rtp} \_ \text{varp}_{r,t,p} \land \text{CAP} \_ \text{BND}_{r,t,p,LO}) \]
\[ + \text{CAP} \_ \text{BND}_{r,t,p,UP'} \times (\text{NOT} \text{rtp} \_ \text{varp}_{r,t,p} \land \text{CAP} \_ \text{BND}_{r,t,p,UP'}) \]

\[ \{ \leq; =; \geq \} \]

\[ \sum_{v \in \text{rtp} \_ \text{cptyr}_{r,t,p}} \left( \text{VAR} \_ \text{Ncap}_{r,v,p} \times (v \in \text{MILESTONYR}) \right) \]
\[ + \text{Ncap} \_ \text{PASTI}_{r,v,p} \times (v \in \text{PASTYEAR}) \]
\[ - \text{VAR} \_ \text{SCAP}_{r,v,t,p} \times ((r, p) \in \text{prc} \_ \text{rcap}) \]

where

\[ \text{COEF} \_ \text{CPT}_{r,v,t,p} \text{ as defined in equation } EQ(l) \_ \text{CAPACT} \]
6.3.19 Equation: EQ(l)_COMBAL

Indices: region (r), period (t), commodity (c), timeslice (s)

Type: Determined by the user-supplied set com_lim. Defaults are:
- \( l = 'G' \) (\( \text{lim} = 'LO' \) in com_lim) for energy carriers \( \text{com}_\text{map}(r,c,'NRG') \), demands \( \text{com}_\text{map}(r,c,'DEM') \), and emissions \( \text{com}_\text{map}(r,c,'ENV') \); yields \( \geq \) type of equation; production has to be greater or equal consumption if no upper bound at the same time
- \( l = 'E' \) (\( \text{lim} = 'FX' \) in com_lim) for materials \( \text{com}_\text{map}(r,c,'MAT') \) and financial commodities \( \text{com}_\text{map}(r,c,'FIN') \); yields = type of equation; production has to be equal consumption if no upper bound at the same time

Related variables: VAR_ACT, VAR_FLO, VAR_COMNET, VAR_COMPR, VAR_IRE, VAR_NCAP, VAR_SIN/OUT, VAR_BLND, VAR_ELAST

Purpose: This equation ensures that at each period and time-slice, the total procurement of a commodity balances its total disposition. A commodity may be procured in several different ways: imported, produced by technologies (activity and capacity based), released at retirement of some investments. A commodity may be disposed of in several other ways: exported, consumed by technologies (activity or capacity based) or by a demand, or “sunk” at investment time of a process. The default type for the balance constraint of an energy carrier and for an emission is \( \geq \), which allows procurement to exceed disposition. This may be important in order to avoid some infeasibilities due to rigid processes with many outputs or inputs. The default sign is = for materials. Both defaults may be modified by the user by the set com_lim.

Remarks:
- The commodity balance is generated for the timeslices \( s \) according to the user defined sets com_tsl or com_ts.
- When there are one or more of the attributes BND/CST/SUB/TAX/CUM relating to production of the commodity, EQE_COMPRD is generated in addition to this equation. EQE_COMPRD simply creates a new variable (VAR_COMPRD) equal to the production part of the LHS of the balance constraint (see expression COMSUP below)
- Similarly, if there are relevant coefficients for the net production of the commodity, the expression VAR_COMNET is created, containing the net production, and used in the RHS (see below).
- Note that CAL_FLOFLO\( (r,t,p,c,s,io) \) table stores the complete expressions (coefficients and variables) giving the flow of each commodity.
- The investment related input flows are assumed to be spread uniformly throughout the commodity lead-time, NCAP_CLED, ending exactly at the end of NCAP_ILED (default value for NCAP_CLED is NCAP_ILED).
- Commodity output flows related to dismantling are assumed to occur uniformly over NCAP_DLIFE, and to start right after NCAP_DLAG (default value: NCAP_DLIFE =1).
• Net/gross production of other commodities can be aggregated to the production side of the commodity balance by using the COM_AGG attribute.

• Capacity-related input/output flows can be defined with NCAP_COM, which has the 'io' index. Examples exist for (physical) consumption as well as release, land use by hydro dams and methane emissions from them, respectively.

EQ_COMBAL reads schematically as follows:

\[ \text{Procurement} - \text{Disposition} \geq \text{COEF_FBRHS} \]

where COEF_FBRHS is 0 for all balance equations, except for demand balances where it is equal to a positive parameter. In addition, COEF_FBRHS is equal to a variable when the equation is used to define the variables VAR_COMPRD or VAR_COMNET.

This is expressed mathematically as the following equation, whose coefficients will be further developed in what follows.

**Interpretation of the results:**

**Primal:** In case of an inequality constraint of the commodity balance, the primal value corresponds to the value which is obtained when all terms with variables are moved to the LHS of the equation and all constants, e.g., terms with the demand parameter COM_PROJ, are moved to the RHS side. The primal value equals the value of the LHS side. Thus, the commodity balance is binding when its primal value equals its RHS constant, it is non-binding, i.e., production exceeds consumption if the primal value is greater than the RHS constant.\(^{43}\)

**Dual:** The dual variable (shadow price) of the commodity balance describes the internal value of the commodity. If the commodity balance is binding, i.e., consumption equals production, the shadow price describes the cost change in the objective function induced by an increase of the commodity demand by one unit. Since the LHS of the commodity balance describes the difference between production and consumption, this additional demand may be covered by an increase in production or by a decrease in consumption. In the first case the shadow price is determined by activities on the supply side of the commodity, while in the latter case saving measures on the demand side of the commodity are setting the shadow price. Note that when a peaking constraint (EQ_PEAK) for the considered commodity exists, the price consumers must pay during peak hours depends not only on the shadow price of the commodity balance but also on the shadow of the peaking constraint (if the flow variable of the consuming technology has the same timeslice resolution as the commodity and the peaking parameters COM_PKFLX=0 and FLO_PKCOI=1, the price to consumers is simply the sum of the two shadow prices; in other cases the dual constraint of the flow variable should be inspected to identify the correct coefficients for the two shadow prices).

---

\(^{43}\) The primal value and the RHS constant of an equation can be found in the GAMS listing file in solution report part. The LEVEL value column corresponds to the primal value, the LOWER level value equals the RHS of a constraint of type \(\geq\) and the UPPER level value equals the RHS of a constraint of a type \(\leq\).
Equation:

\[ EQ(l) \_C_{OMBAl}_{r,t,c,s} \ni \text{rcs\_combal}_{r,t,c,s,bd} \]

\[
\begin{align*}
\sum_{p \in \text{top}_{p,\text{op}/\text{OUT}}} \sum_{\text{vintyr}_{t,ip}} \text{CAL \_FLOFLO}_{r,v,t,p,c,s,\text{OUT}} \\
+ \sum_{\text{pc}_s \text{pc}_s \text{pc}_s \text{pc}_s} \sum_{\text{vintyr}_{t,ip}} \text{CAL \_IRE}_{r,v,t,p,c,s,\text{IMP}} + \text{AUX \_IRE}_{r,t,c,s,\text{OUT}} \\
+ \sum_{\text{pc}_s \text{pc}_s \text{pc}_s \text{pc}_s} \sum_{\text{vintyr}_{t,ip}} \left( \text{VAR \_SOUT}_{r,v,t,p,c,s} \times \left( \text{RS \_FR}_{r,s,c} \times \text{STG \_EFF}_{r,v,p} \right) \right) \\
+ \sum_{\text{pc}_s \text{pc}_s \text{pc}_s \text{pc}_s} \text{BLE \_BAL}_{r,t,c,\text{opr}} \times \text{VAR \_BLND}_{r,t,c,\text{opr}} \times \text{RTCS \_TSFR}_{r,t,c,s,\text{ANNUAL}} \\
\end{align*}
\]

This internal set gives the periods at which the commodity is available (usually all periods, but the user can turn off periods by the set \text{com\_off}), and the timeslices as defined by the user in \text{com\_ts} or \text{com\_ts}.

\text{Output flow of ordinary processes}

\text{Import of the commodity}

\text{Output of blending process; the parameter BLE\_BAL converts the blending streams to energy units}

\text{Flow produced by Technology Capacity}

\text{Flow produced by Technology Investment/Dismantling}

\text{Flow produced by commodity aggregation}

\text{This entire expression is denoted: COMSUP}

(continued on next page)
We now show the detailed calculation of the Right-hand-side
COEF _FBRHS :

DoCase
  Case  \( \text{COM}_\text{BNDNET} \lor \text{COM}_\text{CUMNET} \)
    \( \lor \text{COM}_\text{CSTNET} \lor \text{COM}_\text{SUBNET} \lor \text{COM}_\text{TAXNET} \)
    \( \text{COEF}_\text{FBRHS} = \text{VAR}_\text{COMNET} \)
  Case  \( \text{COM}_\text{BNDPRD} \lor \text{COM}_\text{CUMPRD} \)
    \( \lor \text{COM}_\text{CSTPRD} \lor \text{COM}_\text{SUBPRD} \lor \text{COM}_\text{TAXPRD} \)
    \( \text{COEF}_\text{FBRHS} = \text{VAR}_\text{COMPRD} \)
  Case  \text{COM}_\text{PROJ}
    \( \text{COEF}_\text{FBRHS} = \text{COM}_\text{PROJ} \times \text{COM}_\text{FR} \)
  Otherwise
    \( \text{COEF}_\text{FBRHS} = 0 \)
Endcase
Flow Coefficients related to process activity (VAR_FLO)

\[
\text{CAL}_\text{FLO}LO_{r,y,d,p,c,s,io} \equiv \text{rp}_\text{flo}_{r,p} \land \text{NOT} \text{ rpc} \text{conly}_{r,l,p,c}
\]

\[
= \sum_{s1 \in \text{rtpcs}_\text{varf}_{l,p,c,s1}} \text{VAR} \_\text{FLO}_{r,y,d,p,c,s,sl} \times \text{RTCS} \_\text{TSFR}_{r,l,c,s,sl}
\]

with RTCS_TSFR defined in the following way:

\[
\text{RTCS} \_\text{TSFR}(r,t,c,s,s1)
\]

\[
\text{IF ts_map}_{r,s,s1}
\]

\[
= 1
\]

\[
\text{ELSE}
\]

\[
= \frac{\text{COM} \_\text{FR}_{r,t,c,s}}{\text{COM} \_\text{FR}_{r,t,c,s1}} \text{ if } c \text{ is a demand commodity and COM} \_\text{FR} \text{ is specified},
\]

\[
= \frac{\text{G} \_\text{YRFR}_{r,t,c,s}}{\text{G} \_\text{YRFR}_{r,t,c,s1}} \text{ otherwise}.
\]

The parameter RTCS_TSFR is used to match the timeslice resolution of flow variables (VAR_FLO/VAR_IRE) and commodities. RTCS_TSFR is the coefficient of the flow variable, which is producing or consuming commodity (c), in the commodity balance of c. If timeslice s corresponds to the commodity timeslice resolution of c and timeslice s1 to the timeslice resolution of the flow variable two cases may occur:

1) The flow variables are on a finer timeslice level than the commodity balance (first case in the formula above, ts_map(r,s,s1) is true): in this case the flow variables with timeslices s being below ts in the timeslice tree are summed to give the aggregated flow within timeslice s1. RTCS_TSFR has the value 1.

2) The flow variables are on coarser timeslice level than the commodity balance: in this case the flow variable is split-up on the finer timeslice level of the commodity balance according to the ratio of the timeslice duration of s to s1: RTCS_TSFR has the value = \( \frac{\text{COM} \_\text{FR}(r,s)}{\text{COM} \_\text{FR}(r,s1)} \) for demand commodities and \( \frac{\text{G} \_\text{YRFR}(r,s)}{\text{G} \_\text{YRFR}(r,s1)} \) otherwise. When COM_FR is used, the demand load curve is moved to the demand process. Thus, it is possible to model demand processes on an ANNUAL level and ensure at the same time that the process follows the given load curve COM_FR.
**Inter-regional Flow Coefficients**

\[ CAL_{\text{IRE}}_{r,v,t,p,c,\text{i,e}} \rightarrow \text{rpc}_\text{ire}_{r,p,c,\text{i,e}} \land \text{NOT rpc}_\text{only}_{r,t,p,r} \]

\[ = \sum_{s1\text{rtpcs}_\text{vintyr}_{t,p,r,s1}} \text{VAR}_{\text{IRE}}_{r,v,t,p,c,\text{s1,ie}} \times \text{RTCS}_{\text{TSFR}}_{r,t,c,s1} \]

**Internal set indicating that commodity (c) is imported/exported (ie) via process (p) in/from region (r).**

Adjusts the time-slice of IRE for COM_BAL

**Computes the Auxiliary flows associated with an inter-regional process**

\[ AUX_{\text{IRE}}_{r,t,c,s1,\text{i,o}} \]

\[ = \sum_{(p,\text{com},\text{i,e})} \text{rpc}_\text{ire}_{r,p,\text{com}t,e} \sum_{\text{rtpcs}_\text{vintyr}_{t,p,r,s1}} \text{VAR}_{\text{FLOSUM}}_{r,v,t,p,\text{com},t,e,c,i,o} \]

\[ \times \text{VAR}_{\text{IRE}}_{r,v,t,p,c,\text{s1,ie}} \]

The timeslice (s1) of the flow variable VAR_IRE is below (s) in the timeslice tree.

Since the timeslice (s1) of the flow variable VAR_IRE is above (s) in the timeslice tree, VAR_IRE is apportioned according to the timeslice durations.
### Investment Related Flow Coefficients

**Intermediate Notation:**

\[
BCF = B(v) + NCAP\_ILED - NCAP\_CLED \quad \text{Beginning year of commodity flow}
\]

\[
ECF = B(v) + NCAP\_ILED - 1 \quad \text{Ending year of commodity flow}
\]

*Note that these flows never need to be carried across ‘long’ periods, because the construction never exceeds the end of period v if v is ‘long’.*

\[
COEF\_ICOM:
\]

- **Case IV**

  \[
  \text{if } (v = t) \land (IL + TL < D(t))
  \]

  \[
  = COEF\_RPTINV \times \frac{NCAP\_ICOM_v}{D(t)}
  \]

  where \( COEF\_RPTINV = \left(\frac{D(t) - ILED_t}{TLIFE_t}\right) \)

- **Case I, II, III**

  \[
  = \text{Max}\left(\frac{1 + \text{Min}(ECF, E(t)) - \text{Max}(BCF, B(t))}{D(t)} \times \frac{NCAP\_ICOM_v}{NCAP\_CLED_v,0}\right)
  \]

*Counts the number of investments in a long period*

### Diagrams

- **Case I**
  - NCAP\_CLED
  - \( t \)

- **Case II**
  - \( t \)

- **Case III**
  - \( t \)

- **Case IV**
  - \( t \)
**Dismantling Related Flow Coefficients**

**Intermediate Notation:**

\[ BCF = B(v) + NCAP\_ILED + NCAP\_TLIFE + NCAP\_DLAG \quad \text{Start year of commodity flow.} \]

\[ ECF = B(v) + NCAP\_ILED + NCAP\_TLIFE + NCAP\_DLAG + NCAP\_DLIFE - 1 \quad \text{End year of commodity flow.} \]

**COEF\_OCOM:**

\[
\text{if } t \geq v \land D(v) > IL + TL \land B(t) < E(v) + TL + DLAG + DLIFE
\]

\[
COEF\_RPTINV = \sum_{i=1}^{\text{COEF\_RPTINV}} \max \left( \frac{D(t)}{\max(B(v) + IL + (i \times TL) + DLAG + DLIFE - 1, E(t))}, 0 \right) \times \frac{\text{NCAP\_OCOM}_v}{\text{NCAP\_DLIFE}_v}
\]

\[
\text{else}
\]

\[
= \max \left( \frac{1 + \min(ECF, E(t)) - \max(BCF, B(t))}{D(t)} \times \frac{\text{NCAP\_OCOM}_v}{\text{NCAP\_DLIFE}_v}, 0 \right)
\]

\[
\text{endif}
\]

Either the current period is 'long' or there was a long period that could have investments late enough to be dismantled in 't'.

---

Either the current period is 'long' or there was a long period that could have investments late enough to be dismantled in 't'.
6.3.20 Equation: EQE_COMPRD

Indices: region (r), period (t), commodity (c), timeslice (s)

Type: =

Related variables: VAR_ACT, VAR_FLO, VAR_COMNET, VAR_COMPRD, VAR_IRE, VAR_NCAP, VAR_SOUT, VAR_BLND, VAR_ELAST

Related equations: EQ(l)_COMBAL, EQ(l)_BNDPRD, EQ(l)_CUMPRD, EQ_OBJVAR

Purpose: This equation generates a variable VAR_COMPRD equal to the total supply of the commodity, i.e. import + production (activity and capacity based) + investment-time outflow + dismantling related outflows, in each period and time slice. Note that this excludes demand reduction (in the case of a demand commodity).

Remarks:
- Enables the application of bounds to the annual or cumulative production of commodities. This is also needed to incorporate cost/sub/tax attributes on commodity production.

Equation:

\[ EQE\_COMPRD_{r,t,c,s} = \text{COM\_BNDPRD} \lor \text{COM\_CUMPRD} \]
\[ \lor \text{COM\_CSTPRD} \lor \text{COM\_SUBPRD} \lor \text{COM\_TAXPRD} \]

\[ COMSUP = VAR\_COMPRD_{r,t,c,s} \]

This refers to the term marked “COM\_SUP”, on equation EQ_COMBAL.
6.3.21 Equation: EQ_CUMFLO

Indices: region (r), process (p), commodity (c), year1 (y1), year2 (y2)

Type: =

Related variables: VAR_ACT, VAR_FLO, VAR_CUMFLO

Related equations: EQ_CUMNET, EQ_CUMPRD

Purpose: This equation is generated whenever the input parameter $FLO_{CUM}^{r,p,c,y1,y2}$ or $ACT_{CUM}^{r,p,y1,y2}$ has been specified, for bounding the cumulative amount of process flow or activity. It is also generated when the input parameter $UC_{CUMFLO}$ or $UC_{CUMACT}$ has been specified. It sets the variable $VAR_{CUMFLO}^{r,p,c,y1,y2}$ equal to the cumulative flow/activity expression, to be bounded accordingly or to be referred to in a user constraint.

Remarks:
- The internal set $rpc_{cumflo}^{r,c,y1,y2}$ is set according to any user-defined $FLO_{CUM}^{r,p,c,y1,y2}$, $ACT_{CUM}^{r,p,y1,y2}$, $UC_{CUMFLO}$ or $UC_{CUMACT}$, with the reserved commodity name 'ACT' used for $ACT_{CUM}$ and $UC_{CUMACT}$.

Equation:

$$EQ\_CUMFLO^{r,p,c,y1,y2} \in (rpc_{r,p,c} \land rpc_{cumflo}^{r,c,y1,y2})$$

if \( c \neq 'ACT' \):

$$\sum_{t=T(y2)}^{t=T(y1)} \sum_{v \in T_{vint}^{r,p}} \sum_{r \in rtp_v} \sum_{y \in yint} \sum_{s \in s} \sum_{c \in c} \sum_{p \in p} [Min\{E(t), y2\} - Max\{B(t), y1\} + 1] \times VAR\_FLO^{r,s,p,c,t} = VAR\_CUMFLO^{r,s,p,c,y1,y2}$$

if \( c = 'ACT' \):

$$\sum_{t=T(y2)}^{t=T(y1)} \sum_{v \in T_{vint}^{r,p}} \sum_{r \in rtp_v} \sum_{y \in yint} \sum_{s \in s} \sum_{c \in c} \sum_{p \in p} [Min\{E(t), y2\} - Max\{B(t), y1\} + 1] \times VAR\_ACT^{r,s,p,c,t} = VAR\_CUMFLO^{r,s,p,c,y1,y2}$$

Bounds:

$$VAR\_CUMFLO.LO^{r,p,'ACT',y1,y2} = ACT\_CUM^{r,y1,y2,'LO'}$$

$$VAR\_CUMFLO.UP^{r,p,'ACT',y1,y2} = ACT\_CUM^{r,y1,y2,'UP'}$$

$$VAR\_CUMFLO.FX^{r,p,'ACT',y1,y2} = ACT\_CUM^{r,y1,y2,'FX'}$$

$$VAR\_CUMFLO.LO^{r,p,c,y1,y2} = FLO\_CUM^{r,p,c,y1,y2,'LO'}$$

$$VAR\_CUMFLO.UP^{r,p,c,y1,y2} = FLO\_CUM^{r,p,c,y1,y2,'UP'}$$

$$VAR\_CUMFLO.FX^{r,p,c,y1,y2} = FLO\_CUM^{r,p,c,y1,y2,'FX'}$$
6.3.22 Equation: EQ_CUMNET/PRD

Indices: region (r), year1 (y1), year2 (y2), commodity (c)

Type: =

Related variables: VAR_COMNET/VAR_COMPRD, VAR_CUMCOM

Related equations: EQ(l)_COMBAL, EQE_COMPRD

Purpose: This equation defines a variable representing the cumulative amount of net release or total gross production of a commodity, primarily for bounding the variable according to the bound parameter COM_CUMNET/PRD. The constraint concerns net release/production over an arbitrary number of consecutive years between the year (y1) and year (y2) as given in the parameter COM_CUMNET/PRD.

Remarks:
- It is possible to have multiple cumulative bounds of any type.
- The total time span for calculating the cumulative production need not consist of an exact number of periods.
- The cumulative bounds are expressed annually only.
- The sign of the bound is indicated by the l equation index.

Interpretation of the results:
Primal: The primal value describes the cumulative net release/the cumulative production of commodity c between the years y1 and y2.

Dual: The dual value of the constraint describes the change in the objective function if the bound parameter is increased by one unit. The increase of an upper bound yields a reduction of the total costs (dual value is negative), since the system wants to use more of this commodity. The increase of a lower bound yields an increase of the total costs (dual value is positive), since the system has to be forced to use more of an uncompetitive commodity (the commodity itself or the technologies utilizing it maybe too expensive). The dual value of a cumulative production constraint can also be interpreted as a tax/subsidy that is applied between the years y1 and y2 to reach the same cumulative productions as specified in the bound (the tax/subsidy has to be adjusted by the discount rate).
Equation:

\[
EQ(l) \cdot CUMNET_{r,y_1,y_2,c} \equiv COM \cdot CUMNET_{r,y_1,y_2,c,l}
\]

\[
\sum_{t=T(y_2)}^{2} \sum_{r=T(y_1)}^{1} \left[ \min\{E(t), y_2\} - \max\{B(t), y_1\} + 1 \right] \times VAR \cdot COMNET_{r,t,c,s} = VAR \cdot CUMCOM_{r,c,NET,y_1,y_2}
\]

The internal set \(rtcs\_varc\) gives the periods at which the commodity is available (usually all periods, but the user can turn off periods by the set \coma, and the timeslices as defined by the user in \comts or \comts).

Equation:

\[
EQ(l) \cdot CUMPRD_{r,y_1,y_2,c,s} \equiv COM \cdot CUMPRD_{r,y_1,y_2,c,l}
\]

\[
\sum_{t=T(y_2)}^{2} \sum_{r=T(y_1)}^{1} \left[ \min\{E(t), y_2\} - \max\{B(t), y_1\} + 1 \right] \times VAR \cdot CUMPRD_{r,t,c,s} = VAR \cdot CUMCOM_{r,c,PRD,y_1,y_2}
\]

Bounds:

\[
VAR \cdot CUMCOM\_LO_{r,c,NET,y_1,y_2} = COM \cdot CUMNET_{r,y_1,y_2,c,'LO'}
\]

\[
VAR \cdot CUMCOM\_UP_{r,c,NET,y_1,y_2} = COM \cdot CUMNET_{r,y_1,y_2,c,'UP'}
\]

\[
VAR \cdot CUMCOM\_FX_{r,c,NET,y_1,y_2} = COM \cdot CUMNET_{r,y_1,y_2,c,'FX'}
\]

\[
VAR \cdot CUMCOM\_LO_{r,c,PRD,y_1,y_2} = COM \cdot CUMPRD_{r,y_1,y_2,c,'LO'}
\]

\[
VAR \cdot CUMCOM\_UP_{r,c,PRD,y_1,y_2} = COM \cdot CUMPRD_{r,y_1,y_2,c,'UP'}
\]

\[
VAR \cdot CUMCOM\_FX_{r,c,PRD,y_1,y_2} = COM \cdot CUMPRD_{r,y_1,y_2,c,'FX'}
\]
6.3.23 Equation: EQ_CUMRET

Indices: region (r), vintage year (v), period (t), process (p)

Type: =

Related variables: VAR_RCAP, VAR_SCAP

Related equations: EQ_DSCRET, EQ_SCAP

Purpose: This equation defines the relation between the early retirements of capacity occurring in each period t and the cumulative retirements over all periods $tt \leq t$, by vintage. Its main purpose is to define the early retirements of capacity by each period, in order to be able to bound them directly with the attribute RCAP_BND.

Equation:

$$EQ\_CUMRET_{r,v,t,p} \Leftarrow (rtp\_cptyr\_r,v,t,p \land prec\_rcap\_r,p)$$

$$VAR\_SCAP_{r,v,t,p} = VAR\_RCAP_{r,v,t,p} + \sum_{t-1 \in \{r|rt FTC_{r,v,t,p}\}}^{t} VAR\_SCAP_{r,v,t-1,p}$$
6.3.24 Equation EQ_DSCNCCAP

Indices: region (r), milestone year (t), process (p)

Type: =

Related variables: VAR_DNCAP, VAR_SNCAP, VAR_NCAP

Related equations: EQ_DSCONE

Purpose: The investment variable of the technology p in period t and region r can take only specific unit sizes given by the parameter NCAP_DISC. This equation defines the investment variable to be equal to the sum over the different unit sizes each multiplied by the corresponding decision variable VAR_DNCAP. However, the sister equation EQ_DSCONE restricts this sum to a single term only (i.e. a single unit – of a specific size – is allowed to be invested in at period t). Alternatively, if NCAP_SEMI is defined, the equation defines the investment variable to be equal to the semi-continuous variable VAR_SNCAP.

Remarks:
- The set unit contains the names of capacity blocks/units that can be added, the set contain integer numbers going from ‘0’ to ‘100’. The unit name ‘0’ is used to describe the decision that no capacity should be added.
- The set pre_dscnap(r,p) contains the processes p (in region r) for which the discrete capacity formulation should be used.
- The parameter NCAP_DISC(r,t,p,u) is the allowed capacity size of unit u; e.g. the size of unit ‘1’ could be 50 MW, unit ‘2’ 100 MW and unit ‘3’ 500 MW. The size of unit ‘0’ is automatically set to zero (EPS). If all unit sizes are taken equal, the formulation allows the repeated investment of a basic unit (as many as 100 times, in integer numbers).
- The parameter NCAP_SEMI(r,t,p) can alternatively be used for defining the investment variable VAR_NCAP semi-continuous, with the lower bound defined by NCAP_SEMI, and upper bound by NCAP_BND. If NCAP_BND is not defined, upper bound is assumed equal to the lower bound.
- VAR_DNCAP(r,t,p,u) is a binary decision variable describing whether the capacity unit of technology p should be added in period t or not. Some solvers for mixed-integer problems, as CPLEX or XPRESS, allow the definition of variables as so-called SOS1 sets (special ordered sets) in order to improve the solution process. An SOS1 set is defined as a set of variables of which only one variable can take a non-zero value. VAR_DNCAP is currently defined as an SOS1 variable. Not all solvers support this option, in these cases the variable type should be changed to a binary variable in the file mod_vars.dsc.
Equation:

\[ EQ_{-}DSCNCAP_{r,t,p} \equiv (rp_{dscncap} \land rtp_{r,t,p}) \]

\[
VAR_{-}NCAP_{r,t,p} = \sum_{u \in \text{unit}} \left( VAR_{-}DNCAP_{r,t,p,u} \times NCAP_{-}DSC_{r,t,p,u} \right) + \\
\left( VAR_{-}SNCAP_{r,t,p} \text{ if } NCAP_{-}SEMI_{r,t,p} \text{ given} \right)
\]
6.3.25 Equation: EQ_DSCONE

Indices: region (r), milestone/year (t), process (p)

Type: =

Related variables: VAR_DNCAP, VAR_NCAP

Related equations: EQ_DSCNCAP

Purpose: The equation ensures that only one of the multiple unit sizes allowed for technology p (described by NCAP_DSC(r,t,p,u)) can be added in period t.

Equation

\[ EQ_{-DSCONE_{r,t,p}} \in \left( \varphi_{dscncap_{r,p}} \land rtp_{r,t,p} \right) \]

\[ \sum_{u \in \text{unit}} VAR_{-DNCAP_{r,t,p,u}} = 1 \]

Note that VAR_DNCAP must be declared as a binary variable (taking values 0 or 1 only)
6.3.26 Equation: EQ_DSCRET

Indices: region (r), vintage year (v), period (t), process (p)

Type: =

Related variables: VAR_NCAP, VAR_SCAP, VAR_DRCAP

Related equations: EQ_CUMRET

Purpose: This equation defines the cumulative early retirement variable VAR_SCAP to be a multiple of a user-defined block size, specified by RCAP_BLK. The amount of capacity retired early can thus only take discrete values \( n \times RCAP_BLK, n = 0, 1, 2, \ldots \).

Remarks:
- Because the residual capacity can be defined rather freely by PRC_RESID, a forced component (RTFORC) is added into the cumulative retirements for processes having existing capacities defined with PRC_RESID, corresponding to the trajectory given by PRC_RESID.
- Because it should always be possible to retire the remaining residual capacity in full (regardless of the block size specified), that amount is added as a second alternative block size, which can only be retired in a multiple of 1.

Equation:

\[
EQ\_DSCRET_{r,v,t,p} \equiv (rtp\_cptyr_{r,v,t,p} \land RCAP\_BLK_{r,v,p}) \\
VAR\_SCAP_{r,v,t,p} - RTFORC_{r,v,t,p} = \\
RCAP\_BLK_{r,v,p} \times VAR\_DRCAP_{r,v,t,p} + \\
(NCAP\_PASTI_{r,v,p} - RTFORC_{r,v,t,p}) \times VAR\_DRCAP_{r,v,t,p,1}
\]
6.3.27 Equation: EQ(l)_FLOBND

Indices: region (r), period (t), process (p), commodity group (cg), timeslice (s)

Type: Any type, as determined by the bound index bd of FLO_BND:
- \( l = 'G' \) for bd = ‘LO’ (lower bound) yields \( \geq \).
- \( l = 'E' \) for bd = ‘FX’ (fixed bound) yields \( = \).
- \( l = 'L' \) for bd = ‘UP’ (upper bound) yields \( \leq \).

Purpose: Bound on the sum of process flows in a given commodity group (cg) for a particular process (p) in period (t) and timeslice (s).

Remarks:
- The constraint bounds the flows in a specific period (t) irrespectively of the vintage years of the process capacity.
- The bound can be defined for a single commodity or a group of commodities linked to the process (p). In the latter case, a commodity group (cg) must be defined by the user (through com_gmap).
- The constraint is generated if one of the following conditions is true:
  - Process (p) is vintaged, or
  - The sum of several process flows given by the commodity group (cg), and not only a single process flow, should be bounded, or
  - The timeslice resolution of the flow variables are below the timeslice (s) of the bound parameter.

In other cases, the bound can be directly applied to the corresponding flow variable, so that no extra equation is needed.
- The timeslice level (s) of the bound must be at or higher than the timeslice level of the process flows (rtpcs_vart).
- If FLO_BND is defined for a trade process, the constraint bounds the sum of imports and exports when cg is a single commodity, but net imports if cg is a true commodity group (i.e. is itself not a commodity).

Interpretation of the results:
Primal: If the primal value equals the bound parameter, the constraint is binding.
Dual: The dual value describes for a lower/upper bound the cost increase/decrease in the objective function, if the bound is increased by one unit. It may also be interpreted as subsidy/tax needed to reach the given bound value.

Notation used in formulation:
- \( XS_{cg,ie} \) denotes a sign coefficient for trade flows, such that \( XS_{cg,IMP} = 1 \) for all cg, \( XS_{c,EXP} = 1 \) for all c, and \( XS_{cg,EXP} = -1 \) for all other (true) cg.
Equation:

\[ EQ(l) \_ FLOBND_{r,s,p,cg,ts} = \exists (rtp_{r,s,p} \land FLO\_BND_{r,s,p,cg,ts,bd} \land \left\{ prc\_vint_{r,p} \lor \sum_{c \in \text{com\_gmap}_{r,p,cg}} rs\_below_{r,s,ts} \lor \neg \text{com}_{r,p} \right\} \]

\[ \sum_{c \in \text{com\_gmap}_{r,p,cg}} \sum_{tp \in \text{tertpcs\_var}_{r,p,cg}} \sum_{tp \in \text{tertpcs\_var}_{r,p,cg}} \sum_{vtp \in \text{vint}_{r,p}} \left( \sum_{i \in \text{vint}_{r,p}} \text{VAR\_FLO}_{r,y,t,p,c,ts} \times \text{VAR\_IRE}_{r,y,t,p,c,ts,ie} \times XS_{cg,ie} \right) \]

\[(\leq / \geq / =) \quad FLO\_BND_{r,s,p,cg,ts,bd} \]

where the equation sign is indicated by equation index l based on the bound type bd.
6.3.28 Equation: EQ(l)_FLOFR

Indices: region (r), period (t), process (p), commodity (c), timeslice (s)

Type: Any type, as determined by the bound index bd of FLO_FR:
- l = 'G' for bd = 'LO' (lower bound) yields ≥.
- l = 'E' for bd = 'FX' (fixed bound) yields =.
- l = 'L' for bd = 'UP' (upper bound) yields ≤.

Purpose: 1) Relationship in period (t) between the total annual flow and the flow in a particular timeslice (s) for a specific process (p). This is the standard usage of the FLO_FR parameter, which may be used even for defining a full load curve for a process flow.
2) Relationship in period (t) between the flow level in a particular flow timeslice (s) and the average level under all timeslices under its parent timeslice for a specific process (p). This variant will only be used when FLO_FR is levelized to the flow timeslices (rpcs_var), which is triggered by defining any FLO_FR value for that process flow at the ANNUAL level.

Remarks:
The sign of the equation determines whether the flow in a given timeslice is rigidly (=) or flexibly (≥ ; ≤) linked to the annual flow (or the parent flow level). The constraint bounds the flows irrespectively of the vintage years of the process capacity.

Equation:

Case A: Standard EQ(l)_FLOFR: fraction of flow in total ANNUAL flow

\[
EQ(l)_FLOFR_{r,t,p,c,s} \equiv \left\{ \sum_{ts_map_{r,s,bd}} \sum_{rpcs_var_{t,p,c,s}} FLO_FR_{r,t,p,c,s,bd} \right\}
\]

\[
= \sum_{ts_map_{r,s,bd}} \sum_{rpcs_var_{t,p,c,s}} \left( VAR_{FLO_{r,t,p,c,s}} \times RTCS_{TSFR_{r,t,c,s,bd}} \right)
\]

(≤/≥/=)

\[
= \sum_{ts_map_{r,s,bd}} \sum_{rpcs_var_{t,p,c,s}} \left[ VAR_{FLO_{r,t,p,c,s}} \times FLO_FR_{r,t,p,c,s,bd} \right]
\]

where the equation sign is indicated by equation index l.
Case B: Levelized EQ(l)_FLOFR: flow level in proportion to average level under parent

\[ EQ(l)_FLOFR_{r,t,p,c,s} \in \{rtpcs_var_{r,t,p,c,s} \land FLO_FR_{r,t,p,c,s,bd} \} \]

\[
\sum_{\text{vertp}_v \text{vinty}_r \text{vtp}} \left( \frac{\text{VAR}_r \text{FLO}_{r,v,t,p,c,s}}{G_{\text{YRFR}_{r,t}}} \right) \]

(\(\leq / \geq / =\))

\[
\sum_{\text{vts}_v \text{vinty}_r \text{vtp}} \left( \sum_{\text{sels}_v \text{below}_l \text{vts}} \left( \frac{\sum \text{VAR}_r \text{FLO}_{r,v,t,p,c,s,l}}{G_{\text{YRFR}_{r,t}}} \right) \times \text{FLO}_r \text{FR}_{r,t,p,c,s,bd} \right) \]

where the equation sign is indicated by equation index l.
6.3.29 Equation: EQ(l)_FLMRK

Indices: region (r), period (t), process (p), commodity (c), time-slice (s)

Type: Any type, as determined by the bound index \( bd \) of FLO_MARK/PRC_MARK:
- \( l = \text{'G'} \) for \( bd = \text{'LO'} \) (lower bound) yields \( \geq \).
- \( l = \text{'E'} \) for \( bd = \text{'FX'} \) (fixed bound) yields \( = \).
- \( l = \text{'L'} \) for \( bd = \text{'UP'} \) (upper bound) yields \( \leq \).

Related variables: VAR_FLO, VAR_IRE, VAR_SIN/SOUT, VAR_COMPRD

Related equations: EQ(l)_COMBAL, EQE_COMPRD

Purpose: Relationship to facilitate constraints on the market share of process (p) in the total production of commodity (c). Indicates that the flow of commodity (c) from/to process (p) is bounded by the given fraction of the total production of commodity (c). The time-slice level of the constraint is that of the commodity (c) when using FLO_MARK, and ANNUAL when using PRC_MARK. The same given fraction is applied to all timeslices.

Variables involved:
- \( \text{VAR_FLO}(r,v,t,p,com,s) \) – the average flow to/from a process built in period \( v \), during time-slice \( s \), during each year of period \( t \). The variable for an input flow appears on the consumption side of the balance equation without any coefficients, and the variable for an output flow on the production side multiplied with the commodity efficiency (COM_IE).
- \( \text{VAR_IRE}(r,v,t,p,com,s,ie) \) – the average flow to/from an exchange process built in period \( v \), during time-slice \( s \), during each year of period \( t \). The export variable appears on the consumption side of the balance equation without any coefficients, and the import variable on the production side multiplied by the commodity efficiency (COM_IE).
- \( \text{VAR_SIN/SOUT}(r,v,t,p,c,s) \) – flows entering/leaving a storage process \( p \) storing a commodity \( c \). The variable for charging appears on the consumption side of the balance equation without any coefficients; the import variable on the production side multiplied by both the storage efficiency and commodity efficiency (SGT_EFF, COM_IE).
- \( \text{VAR_COMPRD}(r,t,com,s) \) – variable equal to the total import + production (activity and capacity based) in each period and time slice. This balance is defined by the equation EQE_COMPRD, which is automatically generated for all commodities used in the FLO_MARK or PRC_MARK parameters.

Parameters:
- \( \text{FLO_MARK}(r,t,p,c,l) \) – Market share of single process in total production of commodity \( c \).
- \( \text{PRC_MARK}(r,t,p,grp,c,l) \) – Market share of a group \( grp \) of processes in total production of commodity \( c \).
Remarks:

1. All the FLO_MARK parameters are internally converted to PRC_MARK parameters by the model generator, using the process name of the FLO_MARK parameter as the process group index (grp) in PRC_MARK. Therefore, below references to the parameters are mostly given in terms of PRC_MARK only.

2. Market-share constraints can be specified for standard processes, as well as for exchange and storage processes. For standard processes, the PRC_MARK parameter value can be unambiguously applied to the process flow, and the value should normally be non-negative. However, because exchange and storage processes may have both input and output flows of the same commodity, for these processes the sign of the parameter value determines whether it is applied to the input or output flow, by using the following simple conventional rules:
   - Value ≥ 0: Constraint is applied to the output flow (imports or storage discharge)
   - Value ≤ 0: Constraint is applied to the negative of input flow (exports or storage charge)
   - Value=EPS: Constraint is applied to the net output flow (output–input flow)

   These simple rules provide reasonable flexibility for specifying market share bounds also for exchange and storage processes, in addition to ordinary processes. Although these rules preclude individually bounding the input or output flow to zero, this could always be accomplished by using the IRE_BND, STG_OUTBND, and STG_INBND parameters when necessary.

3. The default timeslice level of the constraint is the commodity timeslice level for the constraints defined by using FLO_MARK by the user, and ANNUAL level for those defined by using the PRC_MARK parameter. For overriding the default, see remark 4 below.

4. The commodity used in the parameter does not actually need to be in the topology, but it should contain some commodity that does exist in the process topology. This feature can be utilized for defining market-share equations at any desired timeslice level. For example, if ELC is a DAYNITE level commodity, the user could define a dummy commodity ELC_ANN that includes ELC as a group member (through COM_GMAP membership), and use the ELC_ANN commodity in the PRC_MARK parameter instead of ELC. The constraint would then be defined at the timeslice level of the ELC_ANN commodity, which is ANNUAL if not explicitly defined.

5. In the equation formulation below, the set mrk_ts_{r,grp,c} denotes the timeslices assigned to the constraints associated with group grp and commodity c in region r, as explained in remarks 3 and 4 above.

6. Zero market shares are either removed (for bound type 'LO') or converted into flow bounds (bound types 'UP' and 'FX'), because the formulation employs inverse values.

Examples:

- Define an upper market share bound of 5% for technology WIND1 in total ELC production in the 2010 period.
- Define an upper market share of 25% for diesel export (through exchange process DSLXHG) of total DSL production in the 2010 period. Note that because the bound is for exports, in this case the parameter value should be negative and the bound type LO instead of UP.

PARAMETER FLO_MARK /
   REG.2010.WIND1.ELC.UP 0.05
   REG.2010.DSLXHG.DSL.LO –0.25
/;
Interpretation of the results:

Primal: If the primal value is zero, the constraint is binding. If the primal value is positive for a lower PRC_MARK bound or negative for an upper bound, the constraint is non-binding.

Dual: The dual value describes for example for a lower bound, the subsidy needed to guarantee the market share of the technology being forced into the market. The subsidy is needed, since the production of the technology is too expensive compared to other competing technologies. The value of the subsidy, which the technology receives, is equal to (1–PRC_MARK)*(dual variable). This subsidy has to be paid by the other technologies producing the same commodity. Thus, the costs of these technologies are increased by the amount PRC_MARK*(dual variable). The constraint can therefore be interpreted as a quota system for the production of a specific technology, e.g. a certificate system for electricity by a wind technology: each non-wind producer has to buy certificates according to the quota. The price of the certificates equals the dual value of the constraint.

Equation:

$$EQ(l)_FLRMK \forall (r,t, grp, c, s) \in \{rts_{r, t, p, c, s} | PRC\_MARK_{r, t, p, c, s, d} \neq 0 \cap mark_{ts_{r, t, p, c, s}}$$

$$\left\{ \begin{array}{c}
\sum_{(com, y, ts) \in RPC_{r, t, p, c, s}} \left[ VAR\_FLO_{r, t, p, com, ts} \times COM\_IE_{r, com, ts} \right] \times \left[ \begin{array}{c}
if\ output
1
if\ input
\end{array} \right] + \\
\sum_{RPC_{r, t, p, c, s}} \left[ \begin{array}{c}
VAR\_IRE_{r, t, p, com, ts, imp} \\
VAR\_SOUT_{r, t, p, com, ts} \times STG\_EFF_{r, p}
\end{array} \right] \times \left[ \begin{array}{c}
COM\_IE_{r, com, ts} \\
0
\end{array} \right] \times \left[ \begin{array}{c}
if\ PRC\_MARK_{r, t, p, c, s, d} \geq 0 \\
if\ PRC\_MARK_{r, t, p, c, s, d} < 0
\end{array} \right] - \\
\left[ \begin{array}{c}
VAR\_SIN_{r, t, p, com, ts} \\
1 \ if \ PRC\_MARK_{r, t, p, c, s, d} \leq 0 \\
0 \ if \ PRC\_MARK_{r, t, p, c, s, d} > 0
\end{array} \right] \times \left[ \begin{array}{c}
RS\_FR_{r, s, is} \\
PRC\_MARK_{r, t, p, c, s, d}
\end{array} \right]
\end{array} \right\}$$
6.3.30 Equations related to exchanges (EQ Ire, EQ IreBND, EQ XBND)

The three equations in this section concern trade between regions. Since these equations involve (directly or indirectly) more than one region, we start their presentation by a complete description of the modeling approach used, which, as we shall see, involves various schemes for representing different types of trade. The description already given in Chapter 4 is also relevant to these equations.

Variables

- VAR Ire(r, v, t, p, c, s, ie)
  
  **Description:** The total amount of traded commodity (c) imported/exported (ie) to/from region (r), through process (p) vintage (v) in each time period (t)

  **Purpose:** The trade variables facilitate trade of commodities between exporting and importing regions

  **Bounds:** The amount of commodity imported to a region from each exporting region can be directly constrained by the IRE_BND parameter.

  **Remarks:**
  - Note that there is a one-to-one correspondence between the VAR Ire variables and the top_ire entries (one variable for the supply region/commodity and one variable for the demand region/commodity for each instance of top_ire).
  - In market-based trade, the VAR Ire variables for the market region describe the net imports to, and exports from, the market region, not the total market volume.
  - There is no variable for the total volume of the commodity market in market-based trade. The total volume can only be addressed by means of UC Ire parameters (summing over all imports to or exports from the market).
  - In market-based trade, only the amount of commodity imported to a region from the market, or exported from the region to the market, can be constrained by the IRE BND parameter. The imports and exports thus cannot be attributed to a specific supply or demand region on the other side of the trade.
  - The amount of commodity exported from / imported to a region may also be limited by various user constraints. However, unless the trade is modeled with bilateral processes, such bounds can only apply to the total exports from or imports to a region, and cannot apply to e.g. imports from a specific region.

There are only three trade equations, namely a generic trade balance equation EQ Ire, and two bounds, EQ(l) IreBND and EQ(l) XBND. The generic balance equation, EQ Ire, can be further divided into two flavors:

A. Balance equations for bilateral and other unidirectional trade into a single destination region (Cases 1 and 2).
B. Balance equations for multidirectional trade from single export region and multi-lateral market-based trade (Cases 3 and 4).
6.3.30.1 Equation EQ_IRE

Indices: region (r), year (t), process (p), commodity (c), timeslice (s)
Type: =
Related variables: VAR_IRE

Related equations: EQ(l)_IREBND, EQ(l)_XBND, EQ(l)_COMBAL, EQ_ACTFLO

Purpose: This equation defines the balance between the imports of each traded commodity (c) into region (r) and the corresponding exports through each exchange process (p) in each time period (t) and timeslice (s) of the process.

Units: Units of commodity traded. Normally PJ for energy, Mton or kton for materials or emissions.

Remarks:
- Flows into individual regions may be limited by the IRE_BND and IRE_XBND parameters.
- The equation has two flavors: The first one is for bilateral and unidirectional trade with a single destination region, and the second is for market-based trade and multidirectional trade from a single source region.
6.3.30.1.1 Case A. Bi-lateral or multilateral unidirectional trade to a single import region

Equation:

\[
EQ\ _{IRE}\ _{r,t,p,c,s} \ni \{r, t, p, c, s \in (rtp_{r,t,p} \land rpcs_{var} r.p.c.s \land rpc_{eqire} r.p.c.s)\}:
\]

\[
\sum_{v \in rtp_{vintyr} r \times v} \sum_{(r_2, s_2) \in inp_{ire2d2, y, v}} \sum_{s_2 \in IRE\ _{TSCVT} r_2, s_2 \times s} \sum_{\{rtcs_{var} f, 2, s_2, l\}} \sum_{rs_{tree} r_2, v, s_2, l} \left\{ \text{VAR} \ _{IRE} r_2, v, t, p, c, s, \text{EXP} \times \text{IRE} \ _{FLO} r_2, v, t, p, c, s, \times \text{RTCS} \ _{TSFR} r_2, r, c, s, l \right\}
\]

Remarks:

- The IRE\ _{TSCVT} conversion coefficients are in practice provided only for some pairs of mapped timeslices between \( r_2 \) and \( r \). Therefore, the timeslice conversion is actually done in two stages: First, the timeslices of the VAR\ _{IRE} variables are converted to the mapped timeslices, and then the mapped timeslices in \( r_2 \) to those in \( r \) as follows:
  - The mapping coefficients IRE\ _{TSCVT} do not have to be provided by the user if the timeslice definitions in both regions are identical.
  - If the timeslice definitions are different, the user provides the mapping coefficients IRE\ _{TSCVT} to convert the timeslice \( s_2 \) in region \( r_2 \) to the timeslice \( s \) in region \( r \). Since the timeslice level of \( s_2 \) may be different from the timeslice level \( ts \) of the exchange variable in region \( r_2 \), the parameter RTCS\ _{TSFR} is used to match \( ts \) and \( s_2 \).
  - Note that the equation is generated for each period in \( rtp \) only, not for each vintage in \( rtp\ _{vintyr} \) as in the original code. This is because \text{prc\ _vint} is region-specific. If \text{prc\ _vint} is set to YES in one region and to NO in another, that would create serious sync problems, if the equation were generated for each vintage in \text{rtp\ _vintyr}. In addition, differences in e.g. NCAP\ _PASTI, NCAP\ _TLIFE, and NCAP\ _AF could create sync problems, even if \text{prc\ _vint} would be set to YES in all regions.
6.3.30.1.2 Case B. Multidirectional and market-based trade between regions.

Equation:

\[
EQ_\text{IRE} \in \mathcal{I}_{r,t,p,c} \ni \{ r, t, p, c, s \in (rtp_{r,t,p} \land rpcs_{var_{r,p,c}} \land rpcs_{eqire_{r,p,c}}) \}:
\]

\[
\sum_{(r_2,c,t) \in \text{top}_{ire_{r_2,t}} \land \text{rpcs}_{market_{r_2}}} \sum_{v_{rtp,vintyr_{r_2}}} \sum_{s_{IRE_{scptvr}} \land \text{rpcs}_{market_{s_2}}} \sum_{c_{IRE_{srsr}}} \left( \frac{\text{VAR}_{IRE_{r_2,t,p,c,s}} \times \text{IRE}_{CCVT_{r_2,c,r,c}} \times \text{RTCS}_{TSFR_{r_2,t,c,s}}}{} \right) \times \left( \frac{\text{VAR}_{IRE_{t_2,s,p,c,s}} \times \text{IRE}_{CCVT_{t_2,c,r,c}} \times \text{RTCS}_{TSFR_{t_2,t,c,s}}}{} \right)
\]

Remarks:

- The IRE_TSCVT conversion coefficients are in practice provided only for some pairs of mapped timeslices between \(r_2\) and \(r\). Therefore, the timeslice conversion is actually done in two stages: First, the timeslices of the VAR_IRE variables are converted to the mapped timeslices, and then the mapped timeslices in \(r_2\) to those in \(r\).

- In the case of market-based trading, \text{prc_aoff} can be used to switch off the entire commodity market for periods that fall within a range of years. It is also possible to specify multiple entries of \text{prc_aoff}, if, for example trading should be possible only between selected years.

- The \text{top_ire} entry between the export and import commodity in the market region itself is automatically defined by the TIMES model generator when necessary, i.e. there is no need to provide it by the user.
6.3.30.2 Equation: EQ(l)_IREBND

Indices: region (r), year (t), commodity (c), timeslice (s), region2 (all_r), import/export (ie)

Type: Any type, as determined by the bound index bd of IRE_BND:
- l = 'G' for bd = ‘LO’ (lower bound) yields ≥.
- l = 'E' for bd = ‘FX’ (fixed bound) yields =.
- l = 'L' for bd = ‘UP’ (upper bound) yields ≤.

Related variables: VAR_IRED

Related equations: EQ_IRED, EQ(l)_XBND, EQ(l)_COMBAL

Description: Sets a bound for the amount of commodity (c) imported/exported (ie) to/from region (r), from/to another region (all_r) in time period (t) and timeslice (s).

Purpose: The equation is optional and can be used to set a bound for a pair-wise inter-regional exchange. The generation of the equation is triggered by the user-specified parameter IRE_BND.

Units: Units of commodity traded. Normally PJ for energy, Mton or kton for materials or emissions.

Type: Set according to the 'l' index in IRE_BND.

Remarks:
- Total trade flows into/from individual regions may be limited by using the IRE_XBND parameter.

Interpretation of the results:
Primal: If the primal value equals the bound parameter, the constraint is binding.
Dual: The dual value describes for a lower/upper bound the cost increase/decrease in the objective function, if the bound is increased by one unit. It may also be interpreted as subsidy/tax needed to reach the given bound value.
Equation:

Case A. Imports from an external region or market region

$$EQ(l) \_ IREBND_{r,t,c,s,all \_ r,ie} \begin{cases} \sum_{r,t,c,s,all \_ r,ie} \sum_{p(\forall 2:TOP _ \_ IRE_{n,t,c,s,p})} \sum_{v \in RTP _ \_ IRETOP_{n,t,c,s,p}} \sum_{s2} \sum_{\forall \_ IRE_{r,t,c,s,p,2,exp}} \times \begin{cases} 1 & \text{if } s2 \in TS _ \_ MAP(r,s,s2) \\ \frac{FR(s)}{FR(s2)} & \text{if } s2 \in RS _ \_ BELOW(r,s2,s) \end{cases} \\ \{\leq,=,\geq\} IRE _ \_ BND_{r,t,c,s,all \_ r,ie} \end{cases}$$

Case B. Imports from an internal non-market region

$$EQ(l) \_ IREBND_{r,t,c,s,all \_ r,ie} \begin{cases} \sum_{r,t,c,s,all \_ r,ie} \sum_{(c2,p)sTOP _ \_ IRE_{n,t,c,s,p}} \sum_{v \in RTP _ \_ IRETOP_{n,t,c,s,p}} \sum_{s1} \sum_{\forall \_ IRE_{all \_ r,t,c,s,p,2,exp}} \times \begin{cases} 1 & \text{if } s1 \in TS _ \_ MAP(r,s,s1) \\ \frac{FR(s)}{FR(s1)} & \text{if } s1 \in RS _ \_ BELOW(r,s1,s) \end{cases} \\ \{\leq,=,\geq\} IRE _ \_ BND_{r,t,c,s,all \_ r,ie} \end{cases}$$
Case C. Exports from a non-market region to an internal or external region

\[ EQ(l) \_ IREBN D_{r,t,c,s,all \_ r,ie} \forall \left\{ r,t,c,s,all \_ r,ie : (RCS \_ COMTS_{r,c,t} \land \exists p : RPC \_ IE_{r,p,c,ie}) \land IRE \_ BND_{r,t,c,s,all \_ r,ie} \right\} : \]

\[ \sum_{p:\exists c:TOP \_ IRE_{r,c,s} \land p} \sum_{s:RS \_ VINTYR_{r,c,p}} \sum_{s_2 \in IRE \_ EXP_{r,v,p,c,s_2,exp}} \left( \begin{array}{c} 1 \text{ if } s_2 \in TS \_ MAP(r,s,s_2) \\ \frac{FR(s)}{FR(s_2)} \text{ if } s_2 \in RS \_ BELOW(r,s_2,s) \end{array} \right) \]

\[ \{\leq;=;\geq\} IRE \_ BND_{r,t,c,s,all \_ r,ie} \]

Case D. Exports from a market region to an internal region

\[ EQ(l) \_ IREBN D_{r,t,c,s,all \_ r,ie} \forall \left\{ r,t,c,s,all \_ r,ie : (RCS \_ COMTS_{r,c,t} \land \exists p : RPC \_ IE_{r,p,c,ie}) \land IRE \_ BND_{r,t,c,s,all \_ r,ie} \right\} : \]

\[ \sum_{(c_2,p) : \exists c \_ TOP \_ IRE_{r,c,s} \land c_2 \land p} \sum_{s:RS \_ VINTYR_{r,c,p}} \sum_{s_2 \in IRE \_ EXP_{all \_ r,v,p,c,s_2,exp}} \]

\[ IRE \_ CCVT_{all \_ r,c_2,r,c} \times IRE \_ TSCVT_{all \_ r,s_2,r,c} \times \left( \begin{array}{c} 1 \text{ if } s_2 \in TS \_ MAP(r,s,s_2) \\ \frac{FR(s)}{FR(s_2)} \text{ if } s_2 \in RS \_ BELOW(r,s_2,s) \end{array} \right) \]

\[ \{\leq;=;\geq\} IRE \_ BND_{r,t,c,s,all \_ r,ie} \]

Remarks:

- The IRE\_TSCVT conversion coefficients are in practice provided only for some pairs of mapped timeslices between all\_r and r. Therefore, the timeslice conversion is actually done in two stages: First, the timeslices of the VAR\_IRE variables are converted to the mapped timeslices, and then the mapped timeslices in all\_r to those in r.
6.3.30.3  Equation:  EQ(l)_XBND

Indices: region (r), year (t), commodity (c), timeslice (s), imp/exp (ie)

Type: Any type, as determined by the bound index bd of IRE_XBND:
- \( l = 'G' \) for \( bd = 'LO' \) (lower bound) yields \( \geq \).
- \( l = 'E' \) for \( bd = 'FX' \) (fixed bound) yields \( = \).
- \( l = 'L' \) for \( bd = 'UP' \) (upper bound) yields \( \leq \).

Related variables: VAR_IRE

Related equations: EQ(l)_IRE, EQ(l)_IREBND, EQ(l)_COMBAL

Description: Bound on the total amount of traded commodity (c) imported/exported (ie) to/from region (all_r) in a period (t) and timeslice (s).

Purpose: This equation bounds inter-regional or exogenous exchanges in a particular region, across all other regions.

Units: Units of commodity traded. Normally PJ for energy, Mton or kton for materials or emissions.

Remarks: Flows into/from individual regions may be limited by the IRE_BND parameter.

Interpretation of the results:
Primal: If the primal value equals the bound parameter, the constraint is binding.
Dual: The dual value describes for a lower/upper bound the cost increase/decrease in the objective function, if the bound is increased by one unit. It may also be interpreted as subsidy/tax needed to reach the given bound value.
Equation:

\[ EQ(1) \_ XBND_{all \_ r,t,c,s,ie} \ni IRE \_ XBND_{all \_ r,t,c,s,ie} \]

- **all\_r is an internal**
  \[
  \sum_{i \in \text{impex}_k} \sum_{s \in \{ \text{rs}_\text{below}_{all \_ r}, \text{rs}_\text{map}_{all \_ r,s} \}} \sum_{n \in \text{tcs}_{all \_ r,s}} \text{vertip}_k \times
  \begin{cases}
  \text{VAR \_ IRE}_{all \_ r,v,t,\text{p}\_1,\text{p}_2,\text{ie}} \times \\
  1 \quad \text{if } s_2 \in \text{ts\_map}_{all \_ r,s} \\
  \frac{\text{G\_YRFR}(s)}{\text{G\_YRFR}(s_2)} \quad \text{if } s_2 \in \text{rs\_below}_{all \_ r,s} 
  \end{cases}
  \]

- **all\_r is an external**
  \[
  \sum_{i \in \text{impex}_k} \sum_{s \in \{ \text{rs}_\text{below}_{all \_ r}, \text{rs}_\text{map}_{all \_ r,s} \}} \sum_{n \in \text{tcs}_{all \_ r,s}} \text{vertip}_k \times
  \begin{cases}
  \text{VAR \_ IRE}_{r,v,t,\text{p}\_1,\text{p}_2,\text{impex}} \times \\
  \text{IRE \_ CVT}_{r,\text{com}_{all \_ r,c}} \\
  \text{IRE \_ TCVT}(r,ts,all \_ r,s)
  \end{cases}
  \]

All regions \( r \) with \( \text{impex} \neq \text{ie} \)

Having import/export from/to \( all \_ r \)
6.3.31 Equations: EQ(l)_INSHR, EQ(l)_OUTSHR

Indices: region (r), year (t), process (p), commodity (c), commodity group (cg), time-slice (s)

Type: Any type, as determined by the bound index bd of FLO_SHAR:
- \( l = 'G' \) for \( bd = 'LO' \) (lower bound) yields \( \geq \).
- \( l = 'E' \) for \( bd = 'FX' \) (fixed bound) yields \( = \).
- \( l = 'L' \) for \( bd = 'UP' \) (upper bound) yields \( \leq \).

Related variables: VAR_FLO, VAR_ACT

Related equations: EQ(l)_COMBAL, EQ_PTRANS, EQ_ACTFLO

Purpose: A market/product allocation constraint equation is generated for each process \( (p) \) for each time period \( (t) \) and each time-slice \( (s) \) in each region (if desired). It ensures that the share of an inflow/outflow of a commodity \( (c) \) is lower/higher/equal a certain percentage of the total consumption/production of this process for a specified commodity group \( (cg) \).

Quality Control Checks:

\[
\sum_{c \in cg} FLO_{_SHAR} r,v,p,c,g,s;LO \forall (FLO_{_SHAR} r,v,p,c,g,s;LO \ni l = "\geq") \leq 1 - \sum_{c \in cg} FLO_{_SHAR} r,v,p,c,g,s;FX
\]

\[
\sum_{c \in cg} FLO_{_SHAR} r,v,p,c,g,s;UP \forall (FLO_{_SHAR} r,v,p,c,g,s;UP \ni l = "\leq") \geq 1 - \sum_{c \in cg} FLO_{_SHAR} r,v,p,c,g,s;FX
\]

\( \forall FLO_{_SHAR} > 0 \)

Remarks:
- Exchanging top(r,p,c,'IN')=Input vs. top(r,p,c,'OUT') = Output in this equation yields EQ(l)_OUTSHR since c is only member of one cg.
- The period index of the parameter FLO_SHAR is related to the vintage period (v) of the process, i.e., if the process is vintaged (prc_vint), a constraint will be generated for each period (t) the installation made in the vintage period (v) still exists (these period pairs are internally provided by the set rtp_vintyr).

Interpretation of the results:
Primal: If the primal value is zero, the constraint is binding. If the primal value is positive for a lower FLO_SHAR bound or negative for an upper bound, the constraint is non-binding.
Dual: The dual value describes, for a lower bound, the subsidy needed to guarantee that the flow is at the given lower bound. The subsidy is needed, since for an output flow the shadow price of the produced commodity is too low to cover the
production costs of the flow variable (for an input flow the opposite is true, the commodity is too expensive to be used in the process). The value of the subsidy that the flow receives is equal to \((1 - FLO\_SHAR)\times\text{(dual variable)}\). This subsidy has to be paid by the other flows forming the denominator in FLO\_SHAR constraint, thus, the costs for these flows are increased by the amount \(FLO\_SHAR\times\text{(dual variable)}\). In a similar way, an upper bound FLO\_SHAR can be interpreted as a tax being added to the costs of a flow.

Equation:

\[
EQ(l)\_IN/OUTSHR_{r,v,t,c,g,s} \iff (c \in cg) \land (t \in rtp\_vintyr_{r,v,t,p}) \land \top_{r,p,c,IN/OUT} \land \\
(s \in rps\_s1_{r,p,s}) \land FLO\_SHAR_{r,v,p,c,g,s,bd} \\
FLO\_SHAR_{r,v,p,c,g,s,hd} \times \sum_{com\in cg} \sum_{rtps\_varf_{l,p,com,s2}} \sum_{VAR \_FLO_{r,v,t,p,com,s2}} \times RTCS\_TSFR_{r,t,p,com,s2} \\
\{-;\leq;\geq\} \\
\sum_{s2\in rtps\_varf_{l,p,com,s2}} VAR\_FLO_{r,v,t,p,com,s2} \times RTCS\_TSFR_{r,t,p,com,s2} \\
\]

See \(EQ(l)\_COMBAL\) for the definition of \(RTCS\_TSFR\).

The set \(rps\_s1\) contains the timeslices of the timeslice level, which is defined to be the finest timeslice level of the process \(prc\_tsl\) and all commodities \(com\_tsl\) linked to the process.
6.3.32 Equation: EQ_PEAK

Indices: region (r), period (t), commodity group (cg), time-slice (s)

Type: \( \geq \)

Related variables: VAR_ACT, VAR_NCAP, VAR_FLO

Related equations: EQ(l)_COMBAL, EQ(l)_CAPACT

Purpose: The commodity peaking constraint ensures that the capacity installed is enough to meet the highest demand in any timeslice, taking into consideration both adjustments to the average demands tracked by the model and a reserve margin requiring excess capacity to be installed.

Remarks:
- In the description below, the production and consumption components resemble those of the EQ(l)_COMBAL commodity balance equation, but with a peak contribution/coincident factor applied to the terms. These factors are process dependent and as such are actually applied within the referenced expression during the summing operation.

Sets and parameters involved:
- \text{com_peak}(r,cg)\) is a flag that a peaking constraint is desired. It is optional if \text{com_pkts}(r,cg,s)\) is provided
- \text{com_pkts}(r,cg,s)\) are the explicit time slices for which peaking constraints are to be constructed. A post-optimization QC check will be done to ensure that the timeslice with highest demand is in said list. Default is all \text{com_ts}(r,c,s)\).
- \text{COM_PKRSV}(r,t,c)\) is the peak reserve margin. Default 0.
- \text{COM_PKFLX}(r,t,c,s)\) is the difference (fluctuation) between the average calculated demand and the actual shape of the peak. Default 0
- \text{FLO_PKCOI}(r,t,p,c,s)\) is a factor that permits increasing the average demand calculated by the model to handle the situation where peak usage is typically higher due to coincidental usage at peak moment (e.g., air condition). Default 1 for each process consuming c. User can prevent a process from contributing to the calculation of the peak by specifying = 0
- \text{NCAP_PKCNT}(r,t,p,s)\) is the amount of capacity (activity) to contribute to the peak. Default 1 for each process producing commodity c. User can prevent a process from contributing to the peak by specifying = EPS
- \text{prc_pkaf}(r,p)\) switch to set \text{NCAP_PKCNT}=\text{NCAP_AF}/1 as default. Default: no
- \text{prc_pkno}(r,p)\) switch to disable process p from contributing to the peak by its capacity, and to disable also assigning the default value of \text{NCAP_PKCNT} for the process.
- \text{rpc_pkc}(r,p,c)\) is an internal set defined to contain those processes (p) and peaking commodities (c) that will be assumed to contribute to the peak by their capacity. Derived by the preprocessor from all those process producing commodity c, which either have c as their primary group PG or have \text{prc_pkaf} defined, but are in neither case included in the set \text{prc_pkno}.
Interpretation of the results:
Primal: When the equation is binding, the primal value of the equation is equal to the RHS constant of the equation, i.e. corresponds to the maximum output from the existing capacity in the peak timeslice, adjusted with the peak reserve requirement. When the equation is non-binding, the primal level also includes the amount of output capacity exceeding the capacity requirements during the timeslice.

Dual: The dual value of the peaking equation describes the premium consumers have to pay in addition to the commodity price (dual variable of EQ(l)_COMBAL) during the peak timeslice. The premium equals 

\[(1+\text{COM}_\text{PKFLX})*\text{FLO}_\text{PKCOI}*\text{RTCS}_\text{TSFR}*(\text{dual variable}).\]

Equation:

\[EQ \_ PEAK_{r,t,c,g,s} \ni \text{com\_peak}_{r,cg} \land s \in \text{com\_pkts}_{r,cg,s} \]

\[\left\{ \begin{array}{l}
\sum_{r,c,p} \left[ \frac{1}{1+\text{COM}_\text{PKRSV}_{r,t,c}} \times \text{COM}_\text{IE}_{r,t,c} \times \sum_{p=\text{imp}_\text{pk}_\text{pk},\text{OUT}^\text{\_ir}_\text{\_pk}_\text{\_pk},\text{IMP}} \left( \begin{array}{l}
\text{NCAP}_\text{PKCNT}_{r,v,p,s} \times \text{COMP}_\text{CPT}_{r,v,t,p} \\
\left( \begin{array}{l}
\text{VAR}_\text{NCAP}_{r,t(v)},p + \text{NCAP}_\text{PASTI}_{r,v,p} \\
\text{VAR}_\text{SCAP}_{r,v,t,p} \times (\text{\_prc\_rcap}_{r,p})
\end{array} \right)
\end{array} \right) \\
\text{G}_\text{YFR}_{r,s} \times \sum_{\text{ver}\_\text{pk}_\text{\_pk}_\text{\_pk},\text{r}_\text{\_p},p} \left[ \begin{array}{l}
\text{PRC}_\text{CAPACT}_{r,p} \times \text{PRC}_\text{ACTFLO}_{r,v,p,c}
\end{array} \right]
\right)
\end{array} \right] \]

else

\[\left\{ \begin{array}{l}
\sum_{r,v,p,s} \text{CAL}_\text{FLOFLO}_{r,v,p,s} \times \text{NCAP}_\text{PKCNT}_{r,v,p,s} \\
+ \sum_{r,v,p,s} \text{VAR}_\text{SOUT}_{r,v,p,s} \times \text{RS}_\text{FR}_{r,s,t,s} \times \text{NCAP}_\text{PKCNT}_{r,v,p,s} \\
+ \sum_{r,v,p,s} \text{CAL}_\text{IRE}_{r,v,p,s} \times \text{IMP}_\text{\_IMP}\text{IMP} \times \text{NCAP}_\text{PKCNT}_{r,v,p,s} \\
- \sum_{r,v,p,s} \text{CAL}_\text{IRE}_{r,v,p,s} \times \text{EXP}_\text{\_EXP} \times \text{NCAP}_\text{PKCNT}_{r,v,p,s}
\end{array} \right]\] if \text{prc\_pkno}_{r,p}
\[
\sum_{c_{cg}} (1 + \text{COM}_\text{PKFLX}_{r,i,c,s}) \times \left[ \sum_{p \in \{\text{op}_{r,p,c,t}, \text{rpc}_{r,p,c,t}\}} \sum_{(v,p,c,t)} \text{VAR}_\text{SIN}_{r,v,i,c,d,s}^t \times \text{RS}_\text{FR}_{r,i,c,d,s} + \sum_{(p,c)} \sum_{\text{rpc}_{r,p,c,t}} \text{VAR}_\text{ELAST}_{r,i,c,s,j,LO^t} + \sum_{j=1}^{\text{COM}_\text{STEP}_{r,c,t}} \text{VAR}_\text{ELAST}_{r,i,c,s,j,UP^t} \right]
\]
6.3.33 Equation: EQ_PTRANS

Indices: region (r), year (y), process (p), commodity group1 (cg1), commodity group2 (cg2), time-slice (s)

Type: =

Related variables: VAR_FLO, VAR_ACT

Related equations: EQ(l)_COMBAL, EQ(l)_INSHR, EQ(l)_OUTSHR, EQ_ACTFLO

Purpose: Allows specifying an equality relationship between certain inputs and certain outputs of a process e.g. efficiencies at the flow level, or the modeling of emissions that are tied to the inputs. It is generated for each process for each time period and each time-slice in each region.

Remarks:
• Internal set rps_s1(r,p,s): The finer of (set of time slices of the most finely divided member of the commodities within the shadow primary group (commodities being not part of primary commodity group and on the process side opposite to the primary commodity group) and the process timeslice level (prc_tsl)).
• The flow variables of the commodities within the primary commodity group are modelled on the process level (prc_tsl). All other flow variables on the timeslice level of rps_s1.
• The internal parameter COEF_PTRAN(r,v,t,p,cg1,c,cg2) is the coefficient of the flow variables of commodity c belonging to the commodity group cg2. While FLO_FUNC(r,v,p,cg1,c,cg2,s) establishes a relationship between the two commodity groups cg1 and cg2, FLO_SUM(r,v,p,cg1,c,cg2,s) can be in addition specified as multiplier for the flow variables of c in cg2.
  COEF_PTRAN is derived from the user specified FLO_FUNC and FLO_SUM parameters based on the following rules:
  o If FLO_FUNC is given between cg1 and cg2 but no FLO_SUM for the commodities c in cg2, it is assumed that the FLO_SUMs are 1.
  o If FLO_SUM is specified but no FLO_FUNC, the missing FLO_FUNC is set to 1.
  o If FLO_SUM(r,v,p,cg1,c,cg2) and FLO_FUNC(r,v,p,cg2,cg1,s) are specified, the reciprocal of FLO_FUNC is taken to calculate COEF_PTRAN.
• FLO_SUMs can only be specified for the flows within one commodity group cg1 or cg2 of EQ_PTRANS between these two commodity groups, but not for both commodity groups at the same time.
• By specifying a SHAPE curve through the parameter FLO_FUNCX(r,v,p,cg1,cg2) the efficiencies FLO_FUNC and FLO_SUM can be described as function of the age of the installation. The internal parameter RTP_FFCX contains the average SHAPE multiplier for the relevant years in a period (those years in which the installed capacity exists).
Interpretation of the results:

Primal: The primal value of the transformation is usually zero.

Dual: Due to the flexibility of the transformation equation the interpretation of its dual value depends on the specific case. For a simple case, a process with one input flow \( c_1 \) and one output flow \( c_2 \) being linked by an efficiency \( FLO_{\text{FUNC}}(c_1,c_2) \), the dual variable, which is being defined as the cost change when the RHS is increased by one unit, can be interpreted as cost change when the efficiency of the process is increased by \( 1/VAR_{\text{FLO}}(r,v,t,p,c_1,s) \):

\[
\begin{align*}
VAR_{\text{FLO}}_{r,v,t,p,c_2,s} - FLO_{\text{FUNC}}_{r,v,t,p,c_1,c_2,s} \times VAR_{\text{FLO}}_{r,v,t,p,c_1,s} &= 1 \\
VAR_{\text{FLO}}_{r,v,t,p,c_2,s} - FLO_{\text{FUNC}}_{r,v,t,p,c_1,c_2,s} \times VAR_{\text{FLO}}_{r,v,t,p,c_1,s} - 1 &= 0 \\
VAR_{\text{FLO}}_{r,v,t,p,c_2,s} - \left( FLO_{\text{FUNC}}_{r,v,t,p,c_1,c_2,s} + \frac{1}{VAR_{\text{FLO}}_{r,v,t,p,c_1,s}} \right) \times VAR_{\text{FLO}}_{r,v,t,p,c_1,s} &= 0
\end{align*}
\]

Equation:

\[
EQ_{\text{PTRANS}}_{r,s,t,p,c_1,c_2,s} \equiv (r,v,t,p) \in (\text{rp\_flo}_{r,p} \land \text{rtp\_vintyr}_{r,v,t,p}) \land s_1 \in \text{rps\_s}s_{r,p,s} \\
\land (s_2 \in \text{ts\_map}_{r,t,s} \land \left( FLO_{\text{SUM}}_{r,t,p,c_2,c_2,s} \lor FLO_{\text{FUNC}}_{r,t,p,c_1,c_2,s} \land \text{NOT}(FLO_{\text{SUM}}_{r,t,p,c_1,c_2,s} \lor FLO_{\text{SUM}}_{r,t,p,c_2,c_1,s}) \right) )
\]

\[
\sum_{c_2 \in \text{ts\_map}_{r,t,s}} \sum_{s_2 \in \text{ts\_map}_{r,t,s}} \sum_{\text{rps\_var}_{r,p,s}} VAR_{\text{FLO}}_{r,v,t,p,c_2,s} \times RTCS_{\text{TSFR}}_{r,c,s,s} =
\]

\[
\sum_{c_1 \in \text{ts\_map}_{r,t,s}} \sum_{s_1 \in \text{ts\_map}_{r,t,s}} \sum_{\text{rps\_var}_{r,p,s}} \left( \text{COEF}_\text{PTRAN}_{r,t,p,c_1,c_2,s} \times VAR_{\text{FLO}}_{r,v,t,p,c_2,s} \times RTCS_{\text{TSFR}}_{r,c,s,s} \right) \\
\times \left( 1 + RTP_{\text{FFCX}}_{r,v,t,p,c_2,s} \times (\text{if\_prec\_vint}_{r,p}) \right)
\]

249
**COEF** = \text{PTRAN}_{r,v,t,p,cg1,c eg2,s} \quad ts \in \text{rpcs\_varc}_{r,p,c,s} \quad = \quad 
\sum_{s \in \text{rpcs\_ts}_{r,p,s}} \left( 1 \times \text{if ts\_map}_{r,s,s} \right) + \frac{G\_YRFR_{r,s}}{G\_YRFR_{r,s}} \times \left( \text{if rs\_below}_{r,s,s} \right) 
\frac{\text{FLO\_FUNC}_{r,v,t,p,cg1,c eg2,s}}{\text{FLO\_FUNC}_{r,v,t,p,cg1,c eg2,s}} \times \left( \text{if FLO\_SUM}_{r,v,t,p,cg1,c eg2,s} \right) \times \left( \text{if FLO\_FUNC}_{r,v,t,p,cg1,c eg2,s} \right) \times 
\left( 1 \times \text{if NOT FLO\_SUM}_{r,v,t,p,cg1,c eg2,s} \right) + \text{FLO\_SUM}_{r,v,t,p,cg1,c eg2,s} 

**Calculation of SHAPE parameter RTP\_FFCX**

**Case A:** Lifetime minus construction time is longer than the construction period

\begin{eqnarray*}
PRC\_YMIN_{r,v,p} &=& B_v + NCAP\_ILED_{r,v,p} \\
PRC\_YMAX_{r,v,p} &=& PRC\_YMIN_{r,v,p} + NCAP\_TLIFE_{r,v,p} - 1 \\
\text{RTP\_FFCX}_{r,v,1,p,cg1,c eg2} &=& \text{FLO\_FUNC}_{r,v,t,p,cg1,c eg2} \\
&=& \sum_{v \in \text{rpv\_vinty}_{r,v,1,p}} \left( \sum_{s \in \text{periody}_{s,v}} \text{SHAPE} \left( \frac{\text{FLO\_FUNC}_{r,v,t,p,cg1,c eg2,1} + \text{MIN} \left( y, PRC\_YMAX_{r,v,p} \right) - PRC\_YMIN_{r,v,p} \right)}{\text{MAX} \left( 1, \text{MIN} \left( E(t), PRC\_YMAX_{r,v,p} \right) - \text{MAX} \left( B(t), PRC\_YMIN_{r,v,p} \right) + 1 \right)} - 1 \right) \\
\end{eqnarray*}

**Case B:** Lifetime minus construction time is shorter than the construction period \implies Investment is repeated in construction period

\begin{eqnarray*}
PRC\_YMAX_{r,v,p} &=& NCAP\_TLIFE_{r,v,p} - 1 \\
\text{RTP\_FFCX}_{r,v,1,p,cg1,c eg2} &=& \text{FLO\_FUNC}_{r,v,t,p,cg1,c eg2} \\
&=& \sum_{v \in \text{rpv\_vinty}_{r,v,1,p}} \left( \frac{\text{SHAPE} \left( \text{FLO\_FUNC}_{r,v,t,p,cg1,c eg2,1} \cdot PRC\_YMAX_{r,v,p} \right)}{PRC\_YMAX_{r,v,p}} - 1 \right) 
\end{eqnarray*}
6.3.34 Equations: EQL_SCAP

Indices: region (r), vintage (v), process (p), indicator (ips)

Type: ≤

Related variables: VAR_ACT, VAR_NCAP, VAR_SCAP

Related equations: EQ_CUMRE

Purpose: Establishes an upper bound for the cumulative retirements and salvaged capacity by process vintage, as well as for the cumulative process activity. The equation is only generated when early retirements are allowed for the process, or if the process is vintaged and a maximum operating life is specified with NCAP_OLIFE.

Notation:
- \( RVPRL_{r,v,p} \) is defined as the time (in years) between the vintage year (v) and the last period t of availability for that vintage: \( RVPRL_{r,v,p} = M(t) - M(v) \).

Equation:

\[
EQL \_ SCAP_{r,v,p,ips} \geq \begin{cases} 
\sum_{t=v+RVPRL_{r,s,p}}^{rtp_{r,v,p}} \left( \text{prc\_rcap}_{r,p} \wedge \left( \neg \text{prc\_vint}_{r,p} \lor \text{obj\_sums}_{r,v,p} \right) \right) \\

\]
6.3.36 Equation: EQ_STGtSS/IPS

Indices: region (r), vintage year (v), period (t), process (p), time-slice (s)

Type: "="

Related variables: VAR_FLO, VAR_ACT

Related equations: EQ(l)_COMBAL, EQ(l)_CAPACT, EQ(l)_STGIN/OUT

Purpose

- The model allows two kinds of storage: inter-period storage (IPS), and storage across time-slices (or time-slice storage TSS). A special type of the TSS storage is a night-storage device, which may have an input commodity different from its output commodity. The input and output commodity of a night-storage device are given by the topology set top.

- Storage processes are special, as they have the same commodity as input and output. Also, all other processes transform energy within their time-slices and time periods. Since topology (with the exception of night-storage devices) does not determine in/out, different variables have to be used for this purpose. Similarly, since the transformation is special, EQ_PTRANS is replaced by new equations for the two types of storage.

Sets:

- prc_stgips(r,p,c): The set of inter-period storage processes. They are forced to operate annually.
- prc_stgtss(r,p,c): The set of time-slice storage processes. A storage process can operate only at one particular time slice level.
- prc_nstts(r,p,s): The set contains the allowed charging timeslices for a night-storage device.

Variables:

- VAR_SIN(r,v,t,p,c,s) – the average in flow to a process built in period v, during time-slice s, during each year of period t. This variable would appear on the consumption side of the balance equation, without any coefficients.
- VAR_SOUT(r,v,t,p,c,s) – the average out flow from a process built in period v, during time-slice s, during each year of period t. This variable would appear on the supply side of the balance equation, multiplied by STG_EFF and COM_IE.
- VAR_ACT(r,v,t,p,s) – the energy stored in a storage process at the beginning of time-slice s (for a timeslice storage) or end of period t (for an inter-period storage). Note that this is a special interpretation of 'activity', to represent 'storage level.' Therefore, EQ_ACTFLO will not be generated for storage processes.

- In EQ_STGtIPS only annual flows are allowed; the timeslice s index is set to ANNUAL in this case.
Equations:
- \( \text{EQ}_\text{STGTSS}(r,t,p,s) \) – transforms input to output for the timeslice storage processes.
- \( \text{EQ}_\text{STGIPS}(r,t,p) \) – transforms input to output for the interperiod storage processes.

Parameters:
- \( \text{STG}_\text{LOSS}(r,v,p,s) \) – annual energy loss from a storage technology, per unit of (average) energy stored.
- \( \text{STG}_\text{CHRG}(r,t,p,s) \) – exogenous charging of a storage technology. For timeslice storage this parameter can be specified for each period, while for interperiod storage this parameter can only be specified for the first period, to describe the initial content of the storage.

6.3.36.1 \( \text{EQ}_\text{STGTSS} \): Storage between timeslices (including night-storage devices):

Equation:

\[
\text{EQ}_\text{STGTSS}_{r,v,t,p,s} \quad \forall (r, v, t, p, s) \in \left( \text{rtp}_\text{vintyr}_{r,v,t,p} \land \text{rps}_\text{stg}_{r,p,s} \land \text{prc}_\text{map}_{r;\text{STG}_{p}} \right)
\]

\[
\text{VAR}_\text{ACT}_{r,v,t,p,s} = \\
\text{VAR}_\text{ACT}_{r,v,t,p,s-1} + \\
\sum_{c \in \text{rpc}_{\text{stg}}} \left( \begin{array}{l}
\text{if } p \text{ is a night - storage device :} \\
\frac{\text{VAR}_\text{SIN}_{r,v,t,p,c,s-1}}{\text{PRC}_\text{ACTFLO}_{r,v,p,c}} \times (\text{if } s-1 \in \text{pre}_\text{nstts}_{r,p,s-1} \land \text{top}_{r,p,c,\text{IN}}) - \\
\frac{\text{VAR}_\text{SOUT}_{r,v,t,p,c,s-1}}{\text{PRC}_\text{ACTFLO}_{r,v,p,c}} \times (\text{if } s-1 \notin \text{pre}_\text{nstts}_{r,p,s-1} \land \text{top}_{r,p,c,\text{OUT}}) \\
\end{array} \right) \\
\text{if } p \text{ is not a night - storage device} \\
+ \sum_{\text{top}_{r,p,c,\text{IN}}} \frac{\text{VAR}_\text{SIN}_{r,v,t,p,c,s-1}}{\text{PRC}_\text{ACTFLO}_{r,v,p,c}} - \sum_{\text{top}_{r,p,c,\text{OUT}}} \frac{\text{VAR}_\text{SOUT}_{r,v,t,p,c,s-1}}{\text{PRC}_\text{ACTFLO}_{r,v,p,c}} \\
- \sum_{ts \in \{s|\text{prc}_\text{ts}_{r,p,c,\text{rs_below}_{r,c}} \}} \text{VAR}_\text{SOUT}_{r,v,t,p,ccs-1} \times \text{RS}_\text{FR}_{r,s-1,ccs} \\
\left[ \frac{\text{VAR}_\text{ACT}_{r,v,t,p,s} + \text{VAR}_\text{ACT}_{r,v,t,p,s-1}}{2} \right] \times \text{STG}_\text{LOSS}_{r,v,p,s} \times \frac{\text{G}_\text{YRFR}_{r,s}}{\text{RS}_\text{STGPRD}_{r,s}} + \text{STG}_\text{CHRG}_{r,t,p,s-1}
\]

6.3.36.2 EQ_STGIPS: Storage between periods

Equation:

\[ EQ\_STGIPS_{r,v,t,p} \ni (rtp\_vintyr_{r,v,t,p} \cap \text{prc\_map}_{r,STK,p}) \]

\[ VAR\_ACT_{r,v,t,p,'ANNUAL'} = \]

\[ \sum_{\text{vert}_{vint} \in rtp\_vintyr_{r,v,t,p} \cap \text{prc\_vint}} \left[ VAR\_ACT_{r,v,t+1,p,'ANNUAL'} \times (1 - STG\_LOSS_{r,v,p,'ANNUAL'})^{D(t)} \right] + \sum_{\text{prc\_vint}} \left[ VAR\_ACT_{r,t+1,t-1,p,'ANNUAL'} \times (1 - STG\_LOSS_{r,v,p,'ANNUAL'})^{D(t)} \right] \]

\[ + \sum_{y \cap \text{period}_{y} \in \text{prc\_stg}_{r,v,p,c}} \left( \sum_{\text{cello}_{p,c}} \frac{VAR\_SIN_{r,v,t,p,c,'ANNUAL'} - PRC\_ACTFLO_{r,v,p,c}}{PRC\_ACTFLO_{r,v,p,c}} \right) \times (1 - STG\_LOSS_{r,v,p,'ANNUAL'})^{(E(t) - y + 0.5)} \]

\[ + \text{STG\_CHRG}_{r,t,p,'ANNUAL'} \text{ (when ORD}(t) = 1) \]
6.3.37 Equations: EQ(l)_STGIN / EQ(l)_STGOUT

Indices: region (r), period (t), process (p), commodity (c), timeslice (s)

Type: Any type, as determined by the bound index \( \text{bd} \) of STGIN/OUT_BND:
- \( l = 'G' \) for \( \text{bd} = 'LO' \) (lower bound) yields \( \geq \).
- \( l = 'E' \) for \( \text{bd} = 'FX' \) (fixed bound) yields \( = \).
- \( l = 'L' \) for \( \text{bd} = 'UP' \) (upper bound) yields \( \leq \).

Related variables: VAR_SIN, VAR_SOUT

Related equations: EQ_STGTSS, EQ_STGIPS

Purpose: Bound on the input/output flow of a storage process of commodity (c) for a particular process (p) in period (t) and timeslice (s).

Remarks:
- The constraint bounds the flows in a specific period (t) irrespectively of the vintage years of the process capacity.
- The constraint is generated if one of the following conditions is true:
  - Process (p) is vintaged, or
  - The timeslice resolution of the flow variables (VAR_SIN/OUT) are below the timeslice (s) of the bound parameter.
In other cases, the bound can be directly applied to the flow variable (VAR_SIN/SOUT), so that no extra equation is needed.
- The timeslice level (s) of the bound must be at or higher than the timeslice level at which the storage operates.

Interpretation of the results:
Primal: If the primal value equals the bound parameter, the constraint is binding.
Dual: The dual value describes for a lower/upper bound the cost increase/decrease in the objective function, if the bound is increased by one unit. It may also be interpreted as subsidy/tax needed to reach the given bound value.

Equation:

\[
\text{EQ}(l)_\text{STGIN} / \text{EQ}(l)_\text{STGOUT} \equiv \left\{ (r,t,p,c) \in \text{rtpc}_{r,p,c} \land \text{STGIN} / \text{OUT}_BND_{r,t,p,c,s,bd} \land s \in \text{rps}_\text{prets}_{r,p,c} \right\}
\]

\[
\sum_{t \in \text{rtpc}_{r,p,c} \land \text{ts_map}_{r,p,c}} \sum_{s \in \text{rps}_\text{prets}_{r,p,c}} \text{VAR}_\text{SIN} / \text{SOUT}_{r,t,p,c,s} \geq (\leq / \geq / =) \ \text{STGIN} / \text{OUT}_BND_{r,t,p,c,s,bd}
\]

All timeslices \( s \) at or above the timeslice level of the process (\text{pre_tsl}).

where the equation sign is indicated by equation index \( l \) based on the bound type \( \text{bd} \).
6.3.38 Equations: EQ_STSBAL

Indices: region (r), vintage (v), period (t), process (p), timeslice (s)

Type: =

Related variables: VAR_ACT, VAR_FLO, VAR_SIN, VAR_SOUT

Related equations: EQ_STGTSS

Purpose: Establishes the balance between different levels of a general timeslice storage.

Equation:

\[
EQ_{-}STSBAL_{r,v,t,p,s} \forall (r,v,t,p,s) \in \{ r_{p,t}, \cap prc_{ts}r,p,s \cap rs_{Below}r,p,s, \}
\]

\[
\sum_{rs_{Below}r,annual} VAR_{-}ACT_{r,v,t,p,s} =
\]

\[
\sum_{rs_{Below}r,annual} \left( VAR_{-}ACT_{r,v,t,p,s-1} + VAR_{-}SOUT_{r,v,t,p,ACT_{s-1}} - \sum_{rs_{Below}r,annual} VAR_{-}SOUT_{r,v,t,p,ACT_{s}} \times RS_{-}FR_{r,s-1,t} - \frac{VAR_{-}ACT_{r,v,t,p,s} + VAR_{-}ACT_{r,v,t,p,s-1}}{STG_{-}LOSS_{r,v,t,p,s} \times G_{YRFR_{r,s}}}{RS_{-}STGPRD_{r,s}} \right)
\]

\[
+ \sum_{s \in \{ annual \}} \left( \sum_{c \in \{ stg\_{inp} \}} \frac{VAR_{-}SIN_{r,v,t,p,c,s}}{PRC_{-}ACTFLO_{r,v,t,p,c}} - \sum_{c \in \{ stg\_{out} \}} \frac{VAR_{-}SOUT_{r,v,t,p,c,s}}{PRC_{-}ACTFLO_{r,v,t,p,c}} \right)
\]

\[
VAR_{-}SOUT_{r,v,t,p,ACT_{s}}
\]
6.3.39 Equations: EQ(l)_UCRTP

Indices: name (uc_n), region (r), period (t), process (p), type (uc_grptype), bound (bd)

Type: Any type, as determined by the bound index bd of uc_dynbnd:
- \( l = 'N' \) for \( bd = 'LO' \) (lower bound) yields \( \geq \).
- \( l = 'N' \) for \( bd = 'UP' \) (upper bound) yields \( \leq \).
- \( l = 'E' \) for \( bd = 'FX' \) (fixed bound) yields \( = \).

Related variables: VAR_ACT, VAR_CAP, VAR_NCAP

Purpose: Dynamic bound on the growth/decay in the capacity (CAP), new capacity (NCAP) or activity level (ACT) of a particular process (p) between period (t) and previous period (t–1).

Remarks:
- The input set uc_dynbnd must be used for flagging the pairs (uc_n,bd) to be reserved for dynamic bound constraints.
- The input parameters UC_CAP, UC_NCAP, and UC_ACT should be used for defining the growth/decay coefficients (side='LHS') and RHS constants (side='RHS').
- The growth/decay coefficients (side='LHS') are given as annual multipliers (e.g. 1.1 for a 10% annual growth). The RHS constants (side='RHS') represent annual absolute values of additional growth/decay.
- The LHS is by default interpolated using option 5. If no LHS is specified, the RHS is by default interpolated with the option 10, like other bounds. However, if the LHS is also specified, the RHS is by default interpolated by the same option as the LHS.
- Whenever any RHS values are specified, the constraints will be generated for those periods for which the RHS is defined after the interpolation/extrapolation. If no RHS is specified, the constraints are generated for the periods that have the LHS defined, but excluding the first period of technology availability.
- In the case of dynamic bounds on the activity (ACT), the UC_ACT values must be specified at the ANNUAL level, and constraint bounds the change in the total activity in a specific period (t), summing over the process vintages and timeslices.
Equations:

Case A. For CAP:

\[ EQ(l) \_ UCRTP_{uc \_ n,r,i,p;CAP\_ bd} \equiv \left( rtp_{r,i,p} \wedge uc\_ dynbnd_{uc \_ n,bd} \wedge \left( \sum_{side} \left( UC\_ CAP_{uc \_ n,side,r,i,p} \right) > 0 \right) \right) \]

\[ VAR\_ CAP_{r,i,p} \{\leq;=} \geq \}

\[ VAR\_ CAP_{r,i-1,p} \times \left( UC\_ CAP_{uc \_ n;LHS\_ r,i,p} \right)^{M(t)-M(t-1)} + UC\_ CAP_{uc \_ n;RHS\_ r,i,p} \times (M(t) - M(t-1)) \]

Case B. For NCAP:

\[ EQ(l) \_ UCRTP_{uc \_ n,r,i,p;NCAP\_ bd} \equiv \left( rtp_{r,i,p} \wedge uc\_ dynbnd_{uc \_ n,bd} \wedge \left( \sum_{side} \left( UC\_ NCAP_{uc \_ n,side,r,i,p} \right) > 0 \right) \right) \]

\[ VAR\_ NCAP_{r,i,p} \{\leq;=} \geq \}

\[ VAR\_ NCAP_{r,i-1,p} \times \left( UC\_ NCAP_{uc \_ n;LHS\_ r,i,p} \right)^{M(t)-M(t-1)} + UC\_ NCAP_{uc \_ n;RHS\_ r,i,p} \times (M(t) - M(t-1)) \]

Case C. For ACT:

\[ EQ(l) \_ UCRTP_{uc \_ n,r,i,p;ACT\_ bd} \equiv \left( rtp_{r,i,p} \wedge uc\_ dynbnd_{uc \_ n,bd} \wedge \left( \sum_{side} \left( UC\_ ACT_{uc \_ n,side,r,i,p;ANNUAL} \right) > 0 \right) \right) \]

\[ \sum_{vertp \_ intyr \_ x \_ grp \_ t \_ r \_ s} \sum_{var \_ ACT_{r,i,p,s}} \{\leq;=} \geq \}

\[ \sum_{vertp \_ intyr \_ x \_ grp \_ t \_ r \_ s} \sum_{var \_ ACT_{r,i-1,p,s}} \times \left( UC\_ ACT_{uc \_ n;LHS\_ r,i,p;ANNUAL} \right)^{M(t)-M(t-1)} \]

\[ + \left( UC\_ ACT_{uc \_ n;RHS\_ r,i,p;ANNUAL} \times (M(t) - M(t-1)) \right) \]
6.4 User Constraints

This section on TIMES User Constraints explains the framework that may be employed by modellers to formulate additional linear constraints, which are not part of the generic constraint set of TIMES, without having to bother with any GAMS programming.

6.4.1 Overview

Indexes: region (r), time period (t), time slice (s), user constraint (uc_n)

Type: Any type, as determined by the bound index bd of $UC_{RHS}(R)(T)(S)(r,uc_n,(t),b)$. 

- $l = 'G'$ for $bd = 'LO$ (lower bound) yields $\geq$.
- $l = 'E'$ for $bd = 'FX$ (fixed bound) yields $\equiv$.
- $l = 'L'$ for $bd = 'UP$ (upper bound) yields $\leq$.

Related variables: VAR_ACT, VAR_CAP, VAR_FLO, VAR_IRE, VAR_NCAP, VAR_COMPRD, VAR_COMNET, VAR_CUMCOM, VAR_CUMFLO, VAR_UPS

Related equations: EQ(l)_COMBAL, EQ(l)_CPT

Purpose: The user constraints in TIMES provide a modeler with a flexible framework to add case-study specific constraints to the standard equation set embedded in TIMES. With the help of the user constraints virtually any possible linear relationship between variables in TIMES can be formulated. Examples of user constraints are quotas for renewables in electricity generation or primary energy consumption, GHG reduction targets, absolute bounds on the minimum amount of electricity generated by various biomass technologies, etc.

Four types of user constraints can be distinguished in TIMES:

- Pure LHS (left hand side) user constraints,
- Timeslice-dynamic user constraints,
- Dynamic user constraints of type (t, t+1), and
- Dynamic user constraints of type (t–1, t).

In addition, the dynamic bound constraints (see EQ_UCRTP) also employ user constraint names and UC_.* attributes, but these constraints are based on prescribed expressions and are thus not considered genuine user constraints.

In the following four subsections, the different types of user constraints are briefly presented. Their mathematical formulations are then presented in a new section.
LHS user constraints

The so-called LHS user constraints have the following main structure:

\[
EQ(l)_{-}UC(R)T(S)_{(r,uc_n,t,s)} \forall \left\{ \frac{UC\_RHS(R)T(S)_{(r,uc_n,t,s)}}{(r,uc_n,t,s)bd} \land \left( r \in uc\_r\_each_{r,uc_n} \right) \right\}
\]

\[
\left( \sum_{uc\_r\_sum_{uc_n}} \right) \left( \sum_{uc\_t\_sum_{uc_n}} \right) \left( \sum_{uc\_ts\_sum_{uc_n}} \right) LHS_{r,t,s} \{ l \geq l \leq \} UC\_RHS(R)T(S)_{(r,uc_n,t,s)}bd
\]

To identify the user constraint, the modeller has to give it a unique name uc_n. The LHS expression LHS_{r,t,s} consists of the sum of various TIMES variables (VAR_ACT, VAR_FLO, VAR_COMPRD, VAR_COMNET, VAR_NCAP, VAR_CAP), multiplied by corresponding coefficients (UC_ACT, UC_FLO, UC_COMPRD, UC_COMCON, UC_NCAP, UC_CAP). The coefficients are input data given by the modeller and serve thus also as an indicator of which variables are being components of the user constraint.

With respect to region r, time period t and timeslice s, the user constraint is either specified for specific regions, periods or timeslices or the expression within the user constraint is summed over subsets of regions, periods and timeslices. In the first case, the regions, periods or timeslices for which the user constraint should be generated are given by the sets uc_r_each, uc_t_each or uc_ts_each, while in the latter case, summation sets are specified by the sets uc_r_sum, uc_t_sum and uc_ts_sum. The corresponding sets uc_x_each/sum are exclusive, so that for example, if uc_t_each has been specified, the set uc_t_sum cannot be specified and vice versa. By choosing uc_x_each/sum also the name and the index domain of the user constraint are specified, e.g. if uc_r_each, uc_t_each and uc_ts_sum are given, the user constraint has the name and index domain EQ(l)_{UCRT_{r,uc_n,t,t}}. It is generated for each region and period specified by uc_r_each and uc_t_each, respectively, and is summing within the user constraint over the timeslices given in uc_ts_each. The name of the RHS constant depends in the same way on the choice of uc_x_each/sum. In the previous example, the RHS constant has the name and index domain UC\_RHSRT_{r,uc_n,t,bd}. The knowledge of these naming rules is important, since the modeller has to give the correct RHS parameter names depending on the choice of uc_x_each/sum when defining a user constraint.

Since for each of the three dimensions (region, period, timeslice), two options (EACH or SUM) exist, this would result in 8 possible combinations of user constraint equations (Figure 5.6). However, the combinations EQ(l)_UCS and EQ(l)_UCRS, which would lead to a constraint being generated for specific timeslices while summing over time periods at the same time, have been considered unrealistic, so that 6 variants remain. It should be noted that the sets uc_r_each/sum, uc_t_each/sum and uc_ts_each/sum can contain an arbitrary combination of elements, e.g. the periods specified in uc_t_each/sum do not have to be consecutive.
The RHS (right hand side) of this category of user constraint consists of a constant $UC\_RHS(R,T)(S)_{(r,uc_n,l),(s),bd}$ which is provided by the modeller. The RHS constant also defines the equation type of the user constraint. If the RHS constant has the index FX, the user constraint is generated as strict equality (=). If the RHS index is LO (respectively UP), the constraint has $\geq$ (respectively $\leq$) inequality sign. It should be noted that a RHS user constraint is only generated when a RHS constant is specified (this feature may be used to easily turn-on/off user constraints between different scenarios).

In addition to the coefficients UC_ACT, UC_FLO, etc. also some model input attributes may be used as coefficient for the variables in a user constraint. The model attribute being used as coefficient in a user constraint is specified by the set $UC\_ATTR_{r,uc_n,LHS,VAR,ATTR}$ with the indicator VAR for the variable (ACT, FLO, IRE, NCAP, CAP, COMNET, COMPRD) and the index ATTR representing the attribute being used (COST, SUB, TAX, DELIV, INVCOST, INVSUB, INVTAX, CAPACT, CAPFLO, NEWFLO, ONLINE, EFF, NET, CUMSUM, PERIOD, GROWTH, see Section 6.4.6 for more information).

Instead of defining different equality types of user constraints depending on the bound type of $UC\_RHS(R,T)(S)_{(r,uc_n,l),(s),bd}$ an alternative formulation can be used in TIMES.
In this formulation a variable $VAR_{-UC}(R)(T)(S)_{(r,uc_{-n,t},s)}$ is created that is set equal to the LHS expression. The RHS bounds are then applied to these variables.

$$EQE_{-UC}(R)(T)(S)_{(r,uc_{-n,t},s)} \forall \left\{ \begin{array}{c} UC_{-RHS}(R)(T)(S)_{(r,uc_{-n,t},s),bd} \land (r \in uc_{-r\_each_{uc_{-n}}}) \\ \land (t \in uc_{t\_each_{uc_{-n}}}) \land (s \in uc_{ts\_each_{uc_{-n}}}) \end{array} \right\}$$

$$LHS_{r,t,s} = VAR_{-UC}(R)(T)(S)_{(r,uc_{-n,t},s)}$$

$$VAR_{-UC}(R)(T)(S)_{LO} = UC_{-RHS}(R)(T)(S)_{(r,uc_{-n,t},s),LO}$$
$$VAR_{-UC}(R)(T)(S)_{UP} = UC_{-RHS}(R)(T)(S)_{(r,uc_{-n,t},s),UP}$$
$$VAR_{-UC}(R)(T)(S)_{FX} = UC_{-RHS}(R)(T)(S)_{(r,uc_{-n,t},s),FX}$$

The alternative formulation is created when the dollar control parameter $VAR_{-UC}$ (see Part III for the use of dollar control parameters) is set to YES by the modeller, while in the default case the first formulation is used.

**Timeslice-dynamic user constraints**

Timeslice-dynamic user constraints establish a relationship between two successive timeslices within a timeslice cycle. The LHS expression $LHS_{r,t,s}$ is generated for timeslice $s$, whereas the RHS expression $RHS_{r,t,s-1}$ is generated for the preceding timeslice $s$–RS_STG($r,s$) under the same parent timeslice. Timeslice-dynamic user constraints of type can thus be written as follows:

$$EQ(l)_{-UCRS} \exists \left\{ \begin{array}{c} UC_{-RHSRTS} \quad (r \in uc_{-r\_each_{uc_{-n}}}) \land (t \in uc_{t\_each_{uc_{-n}}}) \\ \land (s \in ts_{-grp_{r,t,s}} \land \bigcup_{side \_ts_{r,t,s}}) \end{array} \right\}$$

$$LHS_{r,t,s} = \sum_{uc_{ts_{r,t,n}},RHS_{r,t,s}} RHS_{r,t,s-1-\_RS_{STG}(r,s)} + UC_{-RHS}(R)(T)(S)_{(r,uc_{-n,t},s),bd}$$

Timeslice-dynamic user constraints are always specific to a single region and period. To build a timeslice-dynamic user constraint, the modeller must identify the desired timeslice level of the constraint, by using the set $uc_{ts_{r,t,n},side,t}$, and the RHS constants must be defined by using the $UC_{-RHSRTS}$ parameter. The constraint will be genuinely dynamic only if $uc_{ts_{r,t,n}}$ is specified on the RHS. This is the only type of user constraint for which the RHS constant parameter is levelized, according the timeslice level identified by $uc_{ts_{r,t,n}}$. That can make the RHS specification much easier.
Dynamic user constraints

Dynamic user constraints establish a relationship between two consecutive periods. The LHS expression $LHS_{r,t,s}$ is generated for period $t$, whereas the for the RHS expression either the term $RHS_{r,t+1,s}$ corresponding to the period $t+1$, or the term $RHS_{r,t-1,s}$ corresponding to the period $t-1$ is generated, according to the dynamic type.

Dynamic user constraints of type $(t,t+1)$ can thus be written as follows:

$$EQ(l)\_UC(R)SU(S)_{(r)uc\_n,l,(s)} \supseteq \left\{ \begin{array}{l} UC\_RHS(R)T(S)_{(r)uc\_n,l,(s),bd} \wedge (r \in uc\_r\_each_{r,uc\_n}) \\ \wedge (t \in uc\_t\_succ_{r,uc\_n}) \wedge (s \in uc\_ts\_each_{r,uc\_n}) \end{array} \right\}$$

$$\left( \sum_{r \in uc\_r\_sum_{r,uc\_a}} \sum_{s \in uc\_ts\_sum_{uc\_a}} \right) LHS_{r,t,s} \{ l \geq l \leq \} \left( \sum_{r \in uc\_r\_sum_{r,uc\_a}} \sum_{s \in uc\_ts\_sum_{uc\_a}} \right) RHS_{r,t+1,s} +$$

$$UC\_RHS(R)T(S)_{(r)uc\_n,l,(s),bd}$$

Similarly, dynamic user constraints of type $(t-1,t)$ can be written as follows:

$$EQ(l)\_UC(R)SU(S)_{(r)uc\_n,l,(s)} \supseteq \left\{ \begin{array}{l} UC\_RHS(R)T(S)_{(r)uc\_n,l,(s),bd} \wedge (r \in uc\_r\_each_{r,uc\_n}) \\ \wedge (t \in uc\_t\_succ_{r,uc\_n}) \wedge (s \in uc\_ts\_each_{r,uc\_n}) \end{array} \right\}$$

$$\left( \sum_{r \in uc\_r\_sum_{r,uc\_a}} \sum_{s \in uc\_ts\_sum_{uc\_a}} \right) LHS_{r,t,s} \{ l \geq l \leq \} \left( \sum_{r \in uc\_r\_sum_{r,uc\_a}} \sum_{s \in uc\_ts\_sum_{uc\_a}} \right) RHS_{r,t-1,s} +$$

$$UC\_RHS(R)T(S)_{(r)uc\_n,l,(s),bd}$$

To build a dynamic user constraint of type $(t,t+1)$, between the periods $t$ and $t+1$, the modeller identifies the desired set of time periods that will be used as first periods in the pairs $(t, t+1)$. This set is named $uc\_t\_succ$ (note that the sets $uc\_t\_sum$ and $uc\_t\_each$ are not used in the context of dynamic user constraints, and are reserved for the pure LHS user constraints described in the previous section). In addition, the RHS constant parameter must be defined for all of these time periods.

To build a dynamic user constraint of type $(t-1,t)$, between the periods $t-1$ and $t$, the modeller should indicate the desired type by defining for the constraint any UC_ATTR attribute using the 'RHS' side. In addition, the desired set of time periods that will be used as the second period in the pairs$(t-1,t)$ should be identified by defining the RHS constant parameter for those periods $t$.

The choice between the dynamic types $(t,t+1)$ or $(t-1,t)$ is usually only a matter of convenience. However, while using the $(t,t+1)$ type requires explicit specification of $uc\_t\_succ$, for using the $(t-1,t)$ type, any UC_ATTR on the RHS is sufficient to trigger that dynamic type and will cause auto-generation of $uc\_t\_succ$ for all milestone years.
For both types of dynamic constraints, only four combinations with respect to the region and timeslice domain are possible:

- **EQ(l)_UCSU**: dynamic user constraint summing \( r \) over \( uc_r_sum \) and \( s \) over \( uc_ts_sum \).
- **EQ(l)_UCRSU**: dynamic user constraint being generated for each region \( uc_r_each \) and summing \( s \) over \( uc_ts_sum \).
- **EQ(l)_UCRSUS**: dynamic user constraint being generated for each region \( uc_r_each \) and timeslice \( uc_ts_each \).
- **EQ(l)_UCSUS**: dynamic user constraint summing \( r \) over \( uc_r_sum \) and being generated for each timeslice \( s \) in set \( uc_ts_each \).

The input parameters for defining the coefficients, \( UC\_ACT, UC\_FLO, UC\_IRE, UC\_COMCON, UC\_COMNET, UC\_COMPRD, UC\_NCAP \) and \( UC\_CAP \) all have an index \( side \), which can be either LHS or RHS, to identify on which side of the user constraint the corresponding variables should appear. The LHS index corresponds always to the period \( t \), while the RHS index is related either to the \( t+1 \) or the \( t-1 \) term.

As for LHS user constraints, setting the dollar control parameter \( VAR\_UC \) to YES yields a strict equality type of dynamic user constraint (EQE_UCSU, EQE_UCRSU, EQE_UCRSUS, EQE_UCSUS) with the RHS constant replaced by a user constraint variable (\( VAR\_UCT, VAR\_UCRT, VAR\_UCRTS, VAR\_UCTS \)). The bound given by the RHS constant is then applied to the user constraint variable.

**Growth constraints**

Growth (or decay) constraints are a special type of dynamic constraints. A growth constraint may for example express that the capacity increase between two periods is limited by an annual growth rate. So, growth constraints relate variables in one period to the ones in the previous or following period as in dynamic constraints described in the previous section. In growth constraints, however, in addition some of the variable coefficients \( UC\_ACT, UC\_FLO, UC\_IRE, UC\_COMNET, UC\_COMPRD, UC\_NCAP, UC\_CAP \) can represent annual growth (or decay) rates by specifying the set \( UC\_ATTR \) with the index \( ATTR \) being set to GROWTH. This will cause the coefficient of the corresponding variable being interpreted as an annual growth rate. If for example the input information \( UC\_ATTR\_REG1\_G_1\_LHS\_VAR\_ATTR \) is given for the user constraint \( G_1 \), the coefficient \( UC\_CAP\_G_1\_LHS\_REG1\_p \) of the capacity variable of technology \( p \) will be interpreted as annual growth rate and the final coefficient of the variable \( VAR\_CAP \) in the user constraint will be calculated in the following way:

\[
(UC\_CAP_{G_1,LHS,REG1,p})^{(t+1)-M(t)}.
\]

With the help of the input set \( UC\_ATTR \), growth coefficients can be defined for the variables in LHS expression (as in the example) or for the variables in RHS expression. If a coefficient \( UC\_ACT, UC\_FLO \) etc. is greater than one, it represents an annual growth rate, while a coefficient smaller than one describes an annual decay rate.

\[44\]
growth rate is defined for variables on the LHS, the exponent is $M(t+1) - M(t)$, whereas for RHS variables the exponent is equal to $M(t) - M(t+1)$.

If at least one growth coefficient is defined for a LHS variable, the dynamic constraint will be assumed to be of type $(t, t+1)$ described above. In this case, the growth constraints are generated for the period pairs $t$ and $t+1$ for all periods $t$ of the model horizon with the exception of the last period.

If, however, all growth coefficients are specified for the RHS variables, the dynamic constraint will be assumed to be of type $(t-1, t)$, and the growth constraints are now generated for the period pairs $t-1$ and $t$ for all periods of the model horizon. In this alternative RHS formulation, it is possible to introduce boundary conditions that are usually needed for the first period.

**Example of defining a simple growth constraint:**

The annual capacity increase of technology E01 between two periods should not exceed 2% for model covering the three ten-year periods 1990, 2000 and 2010. So one wants to create user constraints expressing:

$$1.02^{10} \times \text{VAR\_CAP}_{\text{REG1}, 1990; E01} + 1 \geq \text{VAR\_CAP}_{\text{REG1}, 2000; E01}$$

$$1.02^{10} \times \text{VAR\_CAP}_{\text{REG1}, 2000; E01} + 1 \geq \text{VAR\_CAP}_{\text{REG1}, 2010; E01}$$

The summand 1 on the LHS expresses an initial capacity value, so that capacity growth can start from this starting point, e.g. if $\text{VAR\_CAP}_{\text{REG1}, 1990; E01}$ is zero, the model can invest at most 1 capacity unit in the year 2000: $1 \geq \text{VAR\_CAP}_{\text{REG1}, 2000; E01}$.

Since growth constraints should be generated for the first two periods, but not the last one, the growth constraint should be of type $(t, t+1)$. The specification of the growth constraint called ‘G_1’ in GAMS looks like:

```plaintext
SET UC_N /
  G_1 /

* Specify growth of capacity on the LHS
SET UC_ATTR /
  REG1.G_1.LHS.CAP.GROWTH /

* Specify growth coefficient for E01 on LHS (period 1) and coefficient * for capacity on RHS (period t+1)
PARAMETER UC_CAP /
  * on the LHS
  G1.LHS.REG1.2000.E01 1.02
  * on the RHS
  G1.RHS.REG1.2000.E01 1

* Specify RHS constant for the years t to have the constraint
PARAMETER UC_RHSRTS /
  REG1.G_1.1990.ANNUAL.LO -1
  REG1.G_1.2000.ANNUAL.LO -1
```

266
One should note that the period index used for the UC_CAP on the LHS is related to the period $t$, while the period index on the RHS is related to the period $t+1$. The RHS UC_RHSRTS constant is provided for the time period $t$ of the LHS.

Since a growth coefficient is specified for the LHS, the user constraint is automatically identified as a dynamic growth constraint, so that the set $\text{uc}_t\_\text{succ}$ does not need to be provided by the user. The constraint will be generated for all periods for which the RHS parameter UC_RHSRTS is given.

In the following section, we give the full descriptions of the available user constraints in each category, along with a reminder of the corresponding variables.

Mathematical descriptions of user constraints

List of user constraints and variables

We first show the complete list of user constraints in the three categories.

The following types of LHS user constraints exist:

- **EQ(l)\_UC_{uc,n}**: user constraint summing over regions $\text{uc}_r\_\text{sum}$, periods $\text{uc}_t\_\text{sum}$ and timeslices $\text{uc}_ts\_\text{sum}$,
- **EQ(l)\_UCR_{r,uc,n}**: user constraint generated for regions $\text{uc}_r\_\text{each}$ and summing over periods $\text{uc}_t\_\text{sum}$ and timeslices $\text{uc}_ts\_\text{sum}$,
- **EQ(l)\_UCT_{uc,n,t}**: user constraint generated for periods $\text{uc}_t\_\text{each}$ and summing over regions $\text{uc}_r\_\text{sum}$ and timeslices $\text{uc}_ts\_\text{sum}$,
- **EQ(l)\_UCRT_{r,uc,n,t}**: user constraint generated for regions $\text{uc}_r\_\text{each}$ and periods $\text{uc}_t\_\text{each}$ and summing over timeslices $\text{uc}_ts\_\text{sum}$,
- **EQ(l)\_UCTS_{uc,n,t,s}**: user constraint generated for periods $\text{uc}_t\_\text{each}$, timeslices $\text{uc}_ts\_\text{each}$ and summing over regions $\text{uc}_r\_\text{sum}$,
- **EQ(l)\_UCRTS_{r,uc,n,t,s}**: user constraint generated for regions $\text{uc}_r\_\text{each}$, periods $\text{uc}_t\_\text{each}$ and timeslices $\text{uc}_ts\_\text{each}$.

The placeholder $l$ reflects the equation type of the user constraint ($l$=E, G or L) corresponding to the bound type of the RHS constant. In case the dollar control parameter VAR_UC is set to YES, the user constraints are always strict equalities ($l$=E) with the RHS constants replaced by the following user constraint variables:

- **VAR\_UC_{uc,n}**: user constraint variable for EQE\_UC,
- **VAR\_UCR_{r,uc,n}**: user constraint variable for EQE\_UCR,
- **VAR\_UCT_{uc,n,t}**: user constraint variable for EQE\_UCT,
- **VAR\_UCRT_{r,uc,n,t}**: user constraint variable for EQE\_UCRT,
- **VAR\_UCTS_{uc,n,t,s}**: user constraint variable for EQE\_UCTS,
- **VAR\_UCRTS_{uc,n,r,t,s}**: user constraint variable for EQE\_UCRTS.

The following types of dynamic user constraints and growth constraints exist:

- **EQ(l)\_UCSU_{uc,n,t}**: user constraint generated for periods $\text{uc}_t\_\text{succ}$, summing over regions $\text{uc}_r\_\text{sum}$ and timeslices $\text{uc}_ts\_\text{sum}$.
• \( EQ(l)_{UCRSU_{r,uc_n,t}} \): user constraint generated for regions \( uc\_r\_each \) and periods \( uc\_t\_succ \) and summing over timeslices \( uc\_ts\_sum \),
• \( EQ(l)_{UCSUS_{uc_n,t,s}} \): user constraint generated for periods \( uc\_t\_succ \), timeslices \( uc\_ts\_each \) and summing over regions \( uc\_r\_sum \),
• \( EQ(l)_{UCRSUS_{r,uc_n,t,s}} \): user constraint generated for regions \( uc\_r\_each \), periods \( uc\_t\_succ \) and timeslices \( uc\_ts\_each \).

The placeholder \( l \) reflects the equation type of the user constraint (\( l=E, G \) or \( L \)) corresponding to the bound type of the RHS constant. In case the dollar control parameter \( VAR\_UC \) is set to YES, the user constraints are always strict equalities (\( l=E \)) with the RHS constants replaced by the following user constraint variables:

• \( VAR\_UCT_{uc_n,t} \): user constraint variable for \( EQE\_UCSU \),
• \( VAR\_UCRT_{r,uc_n,t} \): user constraint variable for \( EQE\_UCRSU \),
• \( VAR\_UCTS_{uc_n,t,s} \): user constraint variable for \( EQE\_UCSUS \),
• \( VAR\_UCRTS_{uc_n,r,t,s} \): user constraint variable for \( EQE\_UCRSUS \).

Sets and parameters related to user constraints

The following sets and parameters are related to the user constraint framework in TIMES.

Sets

Predefined internal sets:
• \( side \): set having the two elements \( LHS \) and \( RHS \) (elements are fixed and not under user control),
• \( uc\_grptype \): set having the elements \( ACT, FLO, IRE, COMCON, COMPRD, NCAP, CAP \) used in the multi-dimensional set \( UC\_ATTR \) (elements are fixed and not under user control),
• \( uc\_name \): set having the following attribute names as elements: \( COST, SUB, TAX, DELIV, INVCOST, INVSUB, INVTA, CAPACT, CAPFLO, NEWFLO, ONLINE, EFF, NET, CUMSUM, PERIOD, GROWTH \) and \( SYNC \) used in the multi-dimensional set \( UC\_ATTR \) (elements are fixed and not under user control).

User-specified sets:
• \( uc\_n \): unique name of the user constraint,
• \( uc\_r\_each_{r,uc_n} \): regions \( r \) for which the user constraint \( uc\_n \) is generated,
• \( uc\_r\_sum_{r,uc_n} \): regions \( r \) being summed over in the user constraint \( uc\_n \),
• \( uc\_t\_each_{r,uc_n,t} \): periods \( t \) for which the user constraint \( uc\_n \) is generated,
• \( uc\_t\_sum_{r,uc_n,t} \): periods \( t \) being summed over in the user constraint \( uc\_n \),
• \( uc\_ts\_each_{r,uc_n,t,s} \): timeslices \( ts \) for which the user constraint \( uc\_n \) is generated,
• \( uc\_ts\_sum_{r,uc_n,t,s} \): timeslices \( ts \) being summed over in the user constraint \( uc\_n \),
• \( uc\_tsl_{r,uc_n,side,tslvl} \): timeslice level \( tslvl \) of user constraint \( uc\_n \),
• **uc_attr**, uc_n, side, uc_grptype, uc_name**: indicator that the attribute **uc_name** on the RHS or LHS side of the user constraint **uc_n** as coefficient of the variable given by **uc_grptype**.

If neither **uc_r_each** nor **uc_r_sum** are given, the default is set to all **uc_r_each** containing all internal regions. In a similar fashion **uc_t_each** being set to all milestoneyears is the default, if neither **uc_t_each** or **uc_t_sum** are specified. The default for the timeslice dimension is **uc_ts_each** being set to all timeslices for which the RHS constants UC_RHSRS or UC_RHSRTS are being specified.

**Parameters**

User-specified coefficients of variables:

- **UC_ACT**uc_n, side, r, t, p, s**: coefficient of the activity variable **VAR_ACT**r, v, t, p, s in the user constraint **uc_n** on the LHS or RHS side,
- **UC_FLO**uc_n, side, r, t, p, c, s**: coefficient of the flow variable **VAR_FLO**r, v, t, p, c, s in the user constraint **uc_n** on the LHS or RHS side,
- **UC_IRE**uc_n, side, r, t, p, c, s, i**: coefficient of the inter-regional exchange variable **VAR_IRE**r, v, t, p, c, s, i in the user constraint **uc_n** on the LHS or RHS side,
- **UC_COMCON**uc_n, side, r, t, c, s**: coefficient of the virtual commodity consumption variable **(VAR_COMPRD**r, t, c, s–**VAR_COMNET**r, t, c, s) in the user constraint **uc_n** on the LHS or RHS side,
- **UC_COMPRD**uc_n, side, r, t, c, s**: coefficient of the gross commodity production variable **VAR_COMPRD**r, t, c, s in the user constraint **uc_n** on the LHS or RHS side,
- **UC_COMNET**uc_n, side, r, t, c, s**: coefficient of the net commodity production variable **VAR_COMNET**r, t, c, s in the user constraint **uc_n** on the LHS or RHS side,
- **UC_CUMACT**uc_n, r, p, y1, y2**: coefficient of the cumulative process activity variable **VAR_CUMFLO**r, p, \(\text{\text{ACT}}, y1, y2\) in the user constraint **uc_n** (only in cumulative constraints),
- **UC_CUMCOM**uc_n, r, type, c, y1, y2**: coefficient of the cumulative commodity net or gross production variable **VAR_CUMCOM**r, type, c, y1, y2 in the user constraint **uc_n**, where type =PRD/NET (only in cumulative constraints),
- **UC_CUMFLO**uc_n, r, p, c, y1, y2**: coefficient of the cumulative process flow variable **VAR_CUMFLO**r, p, c, y1, y2 in the user constraint **uc_n** (only in cumulative constraints),
- **UC_NCAP**uc_n, side, r, t, p**: coefficient of the investment variable **VAR_NCAP**r, t, p in the user constraint **uc_n** on the LHS or RHS side,
- **UC_CAP**uc_n, side, r, t, p**: coefficient of the capacity variable **VAR_CAP**r, t, p in the user constraint **uc_n** on the LHS or RHS side.
User-specified RHS constants:

- **$UC_{RHS}_{uc,n,bd}$**: RHS constant with bound type $bd$ of the user constraint $EQI_{UC_{uc,n}}$ of type 1,
- **$UC_{RHSR}_{r,uc,n,bd}$**: RHS constant with bound type $bd$ of the user constraint $EQI_{UCR_{r,uc,n}}$ of type 1,
- **$UC_{RHST}_{uc,n,t,bd}$**: RHS constant with bound type $bd$ of the user constraint $EQI_{UCT_{uc,n,t}}$ of type 1,
- **$UC_{RHSRT}_{r,uc,n,t,bd}$**: RHS constant with bound type $bd$ of the user constraint $EQI_{UCRT_{r,uc,n,t}}$ of type 1,
- **$UC_{RHSTS}_{uc,n,t,s,bd}$**: RHS constant with bound type $bd$ of the user constraint $EQI_{UCTS_{uc,n,t,s}}$ of type 1,
- **$UC_{RHSRTS}_{r,uc,n,t,s,bd}$**: RHS constant with bound type $bd$ of the user constraint $EQI_{UCRTS_{r,uc,n,t,s}}$ of type 1,
- **$UC_{TIME}_{uc,n,r,t}$**: Defines an additional term in the RHS constant, which is either the time (in years) covered by the user constraint multiplied by $UC_{TIME}$ (for static and cumulative constraints), or the time between the milestone years of the successive periods in the constraint (for dynamic user constraints).
6.4.2 LHS user constraints

Mathematical formulation of LHS user constraints

In the mathematical description of the different variants of LHS user constraints the following placeholders are used for clarity reasons: \( ACT_{r,t,p,s,'LHS'} \), \( FLO_{r,t,p,s,'LHS'} \), \( IRE_{r,t,p,s,'LHS'} \), \( COMPRD_{r,t,s,'LHS'} \), \( COMNET_{r,t,s,'LHS'} \), \( NCAP_{r,t,p,s,'LHS'} \), \( CAP_{r,t,p,s,'LHS'} \), \( CUMCOM_{r} \) and \( CUMFLO_{r} \). For example the placeholder \( ACT_{r,t,p,s,'LHS'} \) includes the part of the user constraint related to the activity variable.

\[
ACT_{r,t,s,'LHS'} = \sum_{(v,p) \in rtp_vintyr, t \in prc_t, p \in ts} \sum_{rtp_r,v\int yr, p \in ts} \left( \sum_{\text{OBJ } \_ \text{ACOST}_{r,t,p,cur}} \right) \text{ if } \text{OBJ } \_ \text{ATTR}_{r,ac_n,'LHS'; \text{ACT}; \text{COST}} \text{ is given}
\]

\[
FLO_{r,t,s,'LHS'} = \sum_{(p,c) \in rtpcs_varf, t \in prc_t, p \in ts} \sum_{rtp_vintyr, v \in t} \left( \sum_{\text{OBJ } \_ \text{FCOST}_{r,t,p,c,cur}} + \sum_{\text{OBJ } \_ \text{FDELV}_{r,t,p,c,cur}} - \sum_{\text{OBJ } \_ \text{FSUB}_{r,t,p,c,cur}} + \sum_{\text{OBJ } \_ \text{FTAX}_{r,t,p,c,cur}} \right) \text{ if } \text{OBJ } \_ \text{ATTR}_{r,ac_n,'LHS'; \text{ACT}; \text{COST}} \text{ is given}
\]
\[ IRE_{r,s,j,LHS} = \sum_{(p,c,s) \in \text{rtpcs_var}_{r,p,c,s}} \sum_{\text{rtp_vintyr}_{r,p,c,s}} \sum_{\text{ircp ire}_{r,p,c,s}} \left[ \begin{array}{c} \text{VAR} \_ \text{IRE}_{r,s,j,p,c,s} \times UC \_ \text{IRE}_{uc\_n,LHS,r,s,j,p,c,s} \times \left( RTCS \_ \text{TSFR}_{r,s,j,p,c,s} \right) \\ + \sum_{\text{cur}r \_\text{deurr}_r, \_\text{cur}} \left( OBJ \_ \text{FCOST}_{r,s,j,p,c,s,cur} \ if \ uc\_\text{attr}_{r,uc\_n,LHS,IRE,COST} \right) \\ + OBJ \_ \text{FDELV}_{r,s,j,p,c,s,cur} \ if \ uc\_\text{attr}_{r,uc\_n,LHS,IRE,DELIV} \\ - OBJ \_ \text{FSUB}_{r,s,j,p,c,s,cur} \ if \ uc\_\text{attr}_{r,uc\_n,LHS,IRE,SUB} \\ + OBJ \_ \text{FTAX}_{r,s,j,p,c,s,cur} \ if \ uc\_\text{attr}_{r,uc\_n,LHS,IRE,TAX} \right) \end{array} \] \]

\[ \text{COMPRD}_{r,s,j,LHS} \]

\[ = \sum_{(c,s) \in \text{rtes_var}_{r,c,s}} \sum_{\text{rtes_var}_{r,c,s}} \sum_{\text{rtes_var}_{r,c,s}} \left[ \begin{array}{c} \text{VAR} \_ \text{COMPRD}_{r,s,j,p,c,s} \times UC \_ \text{COMPRD}_{uc\_n,LHS,r,s,j,p,c,s} \times \left( RTCS \_ \text{TSFR}_{r,s,j,p,c,s} \right) \\ \times \sum_{\text{cur}r \_\text{deurr}_r, \_\text{cur}} \left( OBJ \_ \text{COMPD}_{r,c,s,uc\_cost,cur} \ if \ uc\_\text{attr}_{r,uc\_n,LHS,\text{COMPRD}\_\text{uc\_cost}} \right) \end{array} \] \]

\[ \text{COMNET}_{r,s,j,LHS} \]

\[ = \sum_{(c,s) \in \text{rtes_var}_{r,c,s}} \sum_{\text{rtes_var}_{r,c,s}} \sum_{\text{rtes_var}_{r,c,s}} \left[ \begin{array}{c} \text{VAR} \_ \text{COMNET}_{r,s,j,p,c,s} \times UC \_ \text{COMNET}_{uc\_n,LHS,r,s,j,p,c,s} \times \left( RTCS \_ \text{TSFR}_{r,s,j,p,c,s} \right) \\ \times \sum_{\text{cur}r \_\text{deurr}_r, \_\text{cur}} \left( OBJ \_ \text{COMNT}_{r,c,s,uc\_cost,cur} \ if \ uc\_\text{attr}_{r,uc\_n,LHS,\text{COMNET}\_\text{uc\_cost}} \right) \end{array} \] \]
\[
N_{\text{CAP}}_{\text{r,t,}:\text{LHS}} = \\
\sum_p \left( \text{VAR}_\text{NCAP}_{\text{r,t,p}} \times \text{UC}_\text{NCAP}_{\text{uc,n,}:\text{LHS},\text{r,t,p}} \times \\
\left( \sum_{\text{carer},\text{curr}} \text{OBJ}_\text{ICOST}_{\text{r,t,p,curr}} \quad \text{if UC}_\text{ATTR}_{\text{r,uc,n,}:\text{LHS},\text{CAP},\text{COST}} \quad \text{is given} \\
- \sum_{\text{carer},\text{curr}} \text{OBJ}_\text{ISUB}_{\text{r,t,p,curr}} \quad \text{if UC}_\text{ATTR}_{\text{r,uc,n,}:\text{LHS},\text{CAP},\text{SUB}} \quad \text{is given} \\
+ \sum_{\text{carer},\text{curr}} \text{OBJ}_\text{ITAX}_{\text{r,t,p,curr}} \quad \text{if UC}_\text{ATTR}_{\text{r,uc,n,}:\text{LHS},\text{CAP},\text{TAX}} \quad \text{is given} \right) \right) \\
\sum_p \left( \text{VAR}_\text{CAP}_{\text{r,t,p}} \times \text{UC}_\text{CAP}_{\text{uc,n,}:\text{LHS},\text{r,t,p}} \times \\
\left( \text{PRC}_\text{CAPACT}_{\text{r,p}} \quad \text{if UC}_\text{ATTR}_{\text{r,uc,n,}:\text{LHS},\text{CAP},\text{CAPACT}} \quad \text{is given} \right) \right) \\
\sum_{\text{rc},\text{com},\text{var}} \text{VAR}_\text{CUMCOM}_{\text{r,com,com,}:\text{var},\text{y1,y2}} \times \text{UC}_\text{CUMCOM}_{\text{uc,n,}:\text{com,com,}:\text{var},\text{y1,y2}} \\
\sum_{\text{rpc},\text{cumflo},\text{rpc}} \left( \text{VAR}_\text{CUMFLO}_{\text{r,p,c,y1,y2}} \times \text{UC}_\text{CUMFLO}_{\text{uc,n,r,}:\text{p,c,y1,y2}} \right) + \\
\sum_{\text{rpc},\text{cumflo},\text{rpc}} \left( \text{VAR}_\text{CUMFLO}_{\text{r,p,ACT,y1,y2}} \times \text{UC}_\text{CUMACT}_{\text{uc,n,r,}:\text{p,y1,y2}} \right) 
\]
6.4.2.1 Equation: EQ(l)_{UC} / EQE_{UC}

Indices: user constraint (uc_n)

Related variables: VAR_FLO, VAR_IRE, VAR_NCAP, VAR_CAP, VAR_ACT, VAR_COMPRD, VAR_COMNET, VAR_CUMCOM, VAR_CUMFLO

Purpose: The user constraint EQ(l)_{UC} is a user constraint, which is summing over specified regions (uc_r_sum), periods (uc_t_sum) and timeslices (uc_ts_sum).

Equation:

\[ EQ(l)_{UC_{uc_n}} \in UC_{RHS_{uc_n,lo,\text{ld}}} \land \text{uc_ts_sum}_{uc_n,lo,\text{ld}} \land \text{uc_t_sum}_{uc_n,lo,\text{ld}} \]

\[
\sum_{\text{uc_r_sum}} \sum_{\text{uc_t_sum}} \sum_{\text{uc_ts_sum}} \left( ACT_{r,s,t,\text{LHS}} + FLO_{r,s,t,\text{LHS}} + IRE_{r,s,t,\text{LHS}} + \text{COMNET}_{r,s,t,\text{LHS}} + \text{COMPRD}_{r,s,t,\text{LHS}} \right) \\
+ \sum_{\text{uc_r_sum}} \left( \sum_{\text{uc_t_sum}} \left( NCAP_{r,s,t,\text{LHS}} + CAP_{r,s,t,\text{LHS}} \right) + \left( \text{CUMCOM}_r + \text{CUMFLO}_r \right) \right)
\]

when control parameter VAR_UC is set to NO by the user or is missing:

\[ \{\leq,=,\geq\} \]

\[ UC_{RHS_{uc_n,lo,\text{ld}}} + \sum_{\text{uc_t_sum}} \sum_{\text{uc_r_sum}} UC_{TIME_{uc_n,lo,\text{ld}}} \times D_t \]

When control parameter VAR_UC=YES, the user constraint is created as strict equality and the LHS is set equal to the variable VAR_UC. The bounds UC_RHS are then applied to the variable VAR_UC.

\[ = \]

\[ VAR_{UC_{uc_n}} + \sum_{\text{uc_t_sum}} \sum_{\text{uc_r_sum}} UC_{TIME_{uc_n,lo,\text{ld}}} \times D_t \]

with

\[ VAR_{UCLO_{uc_n}} = UC_{RHS_{uc_n,LO'}} \]

\[ VAR_{UCUP_{uc_n}} = UC_{RHS_{uc_n,UP'}} \]

\[ VAR_{UCFX_{uc_n}} = UC_{RHS_{uc_n,FX'}} \]
6.4.2.2 Equation: EQ(l)_UCR / EQE_UCR

Indices: user constraint (uc_n), region (r)

Related variables: VAR_FLO, VAR_IRE, VAR_NCAP, VAR_CAP, VAR_ACT, VAR_COMPRD, VAR_COMNET, VAR_CUMCOM, VAR_CUMFLO

Purpose: The user constraint EQ(l)_UCR is a user constraint, which is created for each region of uc_r_each and is summing over periods (uc_t_sum) and timeslices (uc_ts_sum).

Equation:

\[
EQ(l)_UCR_{r,uc_n} \ni\ UC\_RHSR_{r,uc_n,bd} \land uc\_ts\_sum_{r,uc_n,s} \land uc\_r\_each_{r,uc_n}
\land uc\_t\_sum_{r,uc_n,d}

\sum_{uc\_t\_sum} \sum_{uc\_ts\_sum} \left( ACT_{r,t,s,LHS} + FLO_{r,t,s,LHS} + IRE_{r,t,s,LHS} + COMNET_{r,t,s,LHS} + COMPRD_{r,t,s,LHS} \right) +
\sum_{uc\_t\_sum} \left( NCAP_{r,t,LHS} + CAP_{r,t,LHS} \right) + \left( CUMCOM_{r} + CUMFLO_{r} \right)
\]

when control parameter VAR_UC=NO:

\{\leq;=;\geq\}

\[
UC\_RHSR_{r,uc_n,d} = \sum_{uc\_t\_sum} UC\_TIME_{r,uc_n,t} \times D_t
\]

When control parameter VAR_UC=YES, the user constraint is created as strict equality and the LHS is set equal to the variable VAR_UCR. The bounds UC_RHSR are then applied to the variable VAR_UCR.

\[
= \quad VAR\_UCR_{r,uc_n} + \sum_{uc\_t\_sum} UC\_TIME_{r,uc_n,t} \times D_t
\]

with

\[
VAR\_UCRLO_{r,uc_n} = UC\_RHSR_{r,uc_n,LO} \quad \\

VAR\_UCRFX_{r,uc_n} = UC\_RHSR_{r,uc_n,FX}
\]
### 6.4.2.3 Equation: \( EQ(l)_UCT / EQ_UCT \)

**Indices:** user constraint (uc_n), period (t)

**Related variables:** VAR_FLO, VAR_IRE, VAR_NCAP, VAR_CAP, VAR_ACT, VAR_COMPRD, VAR_COMNET, VAR_CUMCOM, VAR_CUMFLO

**Purpose:** The user constraint \( EQ(l)_UCT \) is a user constraint, which is created for each period \( uc_t \) and is summing over regions \( uc_r \) and timeslices \( uc_ts \).

**Equation:**

\[
EQ(l)_UCT_{uc_n,t} \geq UC_{RHST_{uc_n,t,bd}} \wedge uc_ts_sum_{r,uc_n} \wedge uc_r_sum_{r,uc_n} \\
\wedge uc_t_each_{r,uc_n}
\]

\[
\sum_{uc_r_sum} \sum_{uc_ts_sum} \left( ACT_{r,j,s,LHS} + FLO_{r,j,s,LHS} + IRE_{r,j,s,LHS} \right) + COMNET_{r,j,s,LHS} + COMPRD_{r,j,s,LHS}
\]

when control parameter VAR_UC=NO:

\[
\left\{ \leq, =, \geq \right\} \\
UC_{RHST_{uc_n,t,bd}} + \sum_{uc_r_sum} UC_{TIME_{uc_n,r,t}} \times D_t
\]

When control parameter VAR_UC=YES, the user constraint is created as strict equality and the LHS is set equal to the variable VAR_UCT. The bounds UC_RHST are then applied to the variable VAR_UCT.

\[
VAR_{UCT_{uc_n,t}} + \sum_{uc_r_sum} UC_{TIME_{uc_n,r,t}} \times D_t
\]

with

\[
VAR_{UCT.LO_{uc_n,t}} = UC_{RHST_{uc_n,t,LO'}} \\
VAR_{UCT.UP_{uc_n,t}} = UC_{RHST_{uc_n,t,UP'}} \\
VAR_{UCT.FX_{uc_n,t}} = UC_{RHST_{uc_n,t,FX'}}
\]
6.4.2.4 Equation: EQ(l)\_UCRT / EQE\_UCRT

Indices: user constraint (uc_n), region (r), period (t)

Related variables: VAR\_FLO, VAR\_IRE, VAR\_NCAP, VAR\_CAP, VAR\_ACT, VAR\_COMPRD, VAR\_COMNET, VAR\_CUMCOM, VAR\_CUMFLO

Purpose: The user constraint EQ(l)\_UCRT is a user constraint, which is created for each region of uc\_r\_each and each period of uc\_t\_each and is summing over timeslices (uc\_ts\_sum).

Equation:

\[ EQ(l)\_UCRT_{r,uc\_n,t} \geq UC\_RHSRT_{r,uc\_n,t,bd} \land uc\_ts\_sum_{r,uc\_n,s} \land uc\_t\_each_{r,uc\_n} \]

\[ \sum_{s \in uc\_ts\_sum} \left( ACT_{r,t,s,LHS'} + FLO_{r,t,s,LHS'} + IRE_{r,t,s,LHS'} + COMNET_{r,t,s,LHS'} + COMPRD_{r,t,s,LHS'} \right) \]

\[ + \left( NCAP_{r,t,LHS'} + CAP_{r,t,LHS'} \right) \]

when control parameter VAR\_UC=NO:

\[ \{\leq;=;\geq\} \]

\[ UC\_RHSRT_{r,uc\_n,t} + UC\_TIME_{uc\_n,t,d} \times D_t \]

When control parameter VAR\_UC=YES, the user constraint is created as strict equality and the LHS is set equal to the variable VAR\_UCRT. The bounds UC\_RHSRT are then applied to the variable VAR\_UCRT.

\[ = VAR\_UCRT_{r,uc\_n,t} + UC\_TIME_{uc\_n,t,d} \times D_t \]

with

\[ VAR\_UCRT\_LO_{r,uc\_n,t} = UC\_RHSRT_{r,uc\_n,t,LO'} \]
\[ VAR\_UCRT\_UP_{r,uc\_n,t} = UC\_RHSRT_{r,uc\_n,t,UP'} \]
\[ VAR\_UCRT\_FX_{r,uc\_n,t} = UC\_RHSRT_{r,uc\_n,t,FX'} \]
6.4.2.5 Equation: \( EQ(l)_{UCRTS} / EQE_{UCRTS} \)

Indices: user constraint (uc_n), region (r), period (t), timeslice (s)

Related variables: VAR_FLO, VAR Ire, VAR_NCAP, VAR_CAP, VAR_ACT, VAR_COMPRD, VAR_COMNET, VAR_CUMCOM, VAR_CUMFLO

Purpose: The user constraint \( EQ(l)_{UCRTS} \) is a user constraint, which is created for each region of \( uc_r_each \), each period of \( uc_t_each \) and each timeslice of \( uc_ts_each \).

\[
EQ(l)_{UCRTS} \quad \text{eqn (r,n,t,s,hd)} \quad uc_ts_each_{r,uc,n} \quad uc_r_each_{r,uc,n} \quad uc_t_each_{r,uc,nd}
\]

\[
\left( \text{ACT}_{r,t,s}/LHS' + FLO_{r,t,s}/LHS' + IRE_{r,t,s}/LHS' \right) + \left( \text{COMNET}_{r,t,s}/LHS' + \text{COMPRD}_{r,t,s}/LHS' \right)
\]

when control parameter VAR_UC=NO:

\[
\{\leq,=,\geq\} \quad UC_{_RHSRTS} r,uc_n,t,s \times UC_{_TIME} \times D_t
\]

When control parameter VAR_UC=YES, the user constraint is created as strict equality and the LHS is set equal to the variable VAR_UCRTS. The bounds UC_RHSRTS are then applied to the variable VAR_UCRTS.

\[
= \quad VAR_{_UCRTS} r,uc_n,t,s + UC_{_TIME} \times D_t
\]

with

\[
VAR_{_UCRTS,LO} r,uc_n,t,s = UC_{_RHSRTS} r,uc_n,t,s,LO
\]

\[
VAR_{_UCRTS,UP} r,uc_n,t,s = UC_{_RHSRTS} r,uc_n,t,s,UP
\]

\[
VAR_{_UCRTS,FX} r,uc_n,t,s = UC_{_RHSRTS} r,uc_n,t,s,FX
\]
6.4.2.6 Equation: \( EQ(l)_{UCTS} / EQE_{UCTS} \)

Indices: user constraint \((uc_n)\), period \((t)\), timeslice \((s)\)

Related variables: \( VAR_FLO, VAR_IRE, VAR_NCAP, VAR_CAP, VAR_ACT, \) \( VAR_COMPRD, VAR_COMNET, VAR_CUMCOM, VAR_CUMFLO \)

Purpose: The user constraint \( EQ(l)_{UCTS} \) is a user constraint, which is created for each period of \( uc_t\_each \) and each timeslice of \( uc_ts\_each \) and is summing over regions \( uc_r\_sum \).

Equation:

\[
EQE_{UCTS}\_{uc_n,t,s,bd} \geq UC\_RHSRTS\_{uc_n,t,s,bd} \wedge uc_t\_each\_{uc_n,s,t} \wedge uc_r\_sum\_{uc_r}\wedge uc_t\_each\_{uc_r\_sum,t}\wedge uc_r\_sum\_{uc_r\_sum,n}
\]

\[
\sum_{uc_r\_sum} \left( \begin{array}{c}
ACT_{r,t,s,LHS} + FLO_{r,t,s,LHS} + IRE_{r,t,s,LHS} \\
+ COMNET_{r,t,s,LHS} + COMPRD_{r,t,s,LHS}
\end{array} \right) 
\]

\[
+ \sum_{uc_r\_sum} \left( NCAP_{r,t,LHS} + CAP_{r,t,LHS} \right)
\]

when control parameter \( VAR\_UC=NO \):

\( \{\leq,=,\geq\} \)

\[
UC\_RHS\_{uc_n,t,s,l} + \sum_{uc_r\_sum} UC\_TIME\_{uc_n,t,r,s} \times D_t
\]

When control parameter \( VAR\_UC=YES \), the user constraint is created as strict equality and the LHS is set equal to the variable \( VAR\_UCTS \). The bounds \( UC\_RHS\_STTS \) are then applied to the variable \( VAR\_UCTS \).

\[
= VAR\_UCTS_{uc_n,t,s} + \sum_{uc_r\_sum} UC\_TIME_{uc_n,t,r,s} \times D_t
\]

with

\[
VAR\_UCTS\_LO_{uc_n,t,s} = UC\_RHS\_{uc_n,t,s,LO} \\
VAR\_UCTS\_UP_{uc_n,t,s} = UC\_RHS\_{uc_n,t,s,UP} \\
VAR\_UCTS\_FX_{uc_n,t,s} = UC\_RHS\_{uc_n,t,s,FX}
\]

279
6.4.3 Timeslice-dynamic user constraints

Mathematical formulation of timeslice-dynamic user constraints

In the mathematical description of the different variants of timeslice-dynamic user constraints, on the LHS the same placeholders can be used as for pure LHS user constraints: \(ACT_{r,t,p,s,'LHS'}, FLO_{r,t,p,s,'LHS'}, IRE_{r,t,p,s,'LHS'}, COMPRD_{r,t,s,'LHS'}, COMNET_{r,t,s,'LHS'}, NCAP_{r,t,p,s,'LHS'}, \) \(CAP_{r,t,p,s,'LHS'}\). The LHS placeholder expressions are identical to those of LHS user constraints.

On the RHS (preceding timeslice \(ds = s - \text{RS\_STG}(r,s)\)), the following placeholders can be used: \(ACT_{r,t,p,ds,'RHS'}, FLO_{r,t,p,ds,'RHS'}, IRE_{r,t,p,ds,'RHS'}, COMPRD_{r,ds,'RHS'}, COMNET_{r,ds,'RHS'}, NCAP_{r,t,ds,'RHS'}, \) \(CAP_{r,t,ds,'RHS'}\). The RHS placeholder expressions can be written by replacing in them the timeslice index \(s\) by \(d(s)\).

Note that the timeslice-specific terms in the equation are all divided by \(G_{YRFR_{r,s}}\) in order to make it easy to combine flow and capacity terms in the constraint.

6.4.3.1 Equation: \(\text{EQ}(l)\_UCRS / \text{EQE}\_UCRS\)

Indices: user constraint (\(uc\_n\)), period (\(t\)), timeslice (\(s\))

Related variables: VAR_FLO, VAR_IRE, VAR_NCAP, VAR_CAP, VAR_ACT, VAR_COMPRD, VAR_COMNET

Purpose: The timeslice-dynamic constraint \(\text{EQ}(l)\_UCRS\) establishes a constraint between two successive timeslices \(s\) and \(d(s) = s - \text{RS\_STG}(r,s)\). The constraint is generated for all regions \(r\) in the set \(uc\_r\_each\), all periods \(t\) in the set \(uc\_t\_each\), and for each timeslice on the timeslice level defined by \(uc\_tsl\), such that also have the corresponding \(UC\_RHSRT_{r,uc\_n,t,s,bd}\) specified.

Equation:

\[
\text{EQ}(l)\_UCRS_{r,uc\_n,t,tsl,s} \rightarrow UC\_RHSRT_{r,uc\_n,t,tsl,s} ^uc\_r\_each \land uc\_t\_each \land (s \in \{ts | ts\_grp_{r,tsl,t} \land \bigcup_{side} uc\_tsl_{r,uc\_n,side,tsl}\})
\]

\[
\left( ACT_{r,t,s,'LHS'} + FLO_{r,t,s,'LHS'} + IRE_{r,t,s,'LHS'} \right) \times \frac{1}{G_{YRFR_{r,s}}} + \left( NCAP_{r,t,'LHS'} + CAP_{r,t,'LHS'} \right)
\]

When control parameter \(\text{VAR\_UC}=\text{NO}\):

\(\{s \leq s; s \geq \}\)
$UC\_RHSRTS_{r,\text{uc}_n,t,s,l} + UC\_TIME_{\text{uc}_n,r,t} \times D_t$

\[
\left( \frac{ACT_{r,t,d(s),\text{RHS}'} + FLO_{r,t,d(s),\text{RHS}'} + IRE_{r,t,d(s),\text{RHS}'} + COMNET_{r,t,d(s),\text{RHS}'} + COMPRD_{r,t,d(s),\text{RHS}'} \times 1}{G\_YRFR_{r,d(s)}} \right)
\]

if $uc\_tsl_{r,\text{uc}_n,\text{RHS}'_s}$

When control parameter VAR\_UC=YES, the user constraint is created as strict equality and the RHS constant UC\_RHSRTS is replaced by the variable VAR\_UCRTS. The bounds UC\_RHSRTS are then applied to the variable VAR\_UCRTS.

\[
\text{VAR\_UCRTS}_{r,\text{uc}_n,t,s} + UC\_TIME_{\text{uc}_n,r,t} \times D_t
\]

\[
\left( \frac{ACT_{r,t,d(s),\text{RHS}'} + FLO_{r,t,d(s),\text{RHS}'} + IRE_{r,t,d(s),\text{RHS}'} + COMNET_{r,t,d(s),\text{RHS}'} + COMPRD_{r,t,d(s),\text{RHS}'} \times 1}{G\_YRFR_{r,d(s)}} \right)
\]

if $uc\_tsl_{r,\text{uc}_n,\text{RHS}'_s}$

with

$VAR\_UCRTS\_LO_{r,\text{uc}_n,t,s} = UC\_RHSRTS_{r,\text{uc}_n,t,s,\text{LO}'}$

$VAR\_UCRTS\_UP_{r,\text{uc}_n,t,s} = UC\_RHSRTS_{r,\text{uc}_n,t,s,\text{UP}'}$

$VAR\_UCRTS\_FX_{r,\text{uc}_n,t,s} = UC\_RHSRTS_{r,\text{uc}_n,t,s,\text{FX}'}$

281
6.4.4 Dynamic user constraints of type (t,t+1)

Mathematical formulation of dynamic user constraints and growth constraints of type (t,t+1)

In the mathematical description of the dynamic user constraints and growth constraints of type (t, t+1), the following placeholders are used for variable terms on the LHS (period t):

- \( \text{ACT\_GROW}_{r,t,s,\text{LHS}} \)
- \( \text{FLO\_GROW}_{r,t,s,\text{LHS}} \)
- \( \text{IRE\_GROW}_{r,t,s,\text{LHS}} \)
- \( \text{COMPRD\_GROW}_{r,t,s,\text{LHS}} \)
- \( \text{COMNET\_GROW}_{r,t,s,\text{LHS}} \)
- \( \text{NCAP\_GROW}_{r,t,p,\text{LHS}} \)

and on the RHS (period t+1):

- \( \text{ACT\_GROW}_{r,t+1,s,\text{RHS}} \)
- \( \text{FLO\_GROW}_{r,t+1,s,\text{RHS}} \)
- \( \text{IRE\_GROW}_{r,t+1,s,\text{RHS}} \)
- \( \text{COMPRD\_GROW}_{r,t+1,s,\text{RHS}} \)
- \( \text{COMNET\_GROW}_{r,t+1,s,\text{RHS}} \)
- \( \text{NCAP\_GROW}_{r,t+1,p,\text{RHS}} \)

The expressions for the variable terms on the LHS can be written as follows:

\[
\text{ACT\_GROW}_{r,t,s,\text{LHS}} = \\
\sum_{(p,v)\in\text{prvnty}_{n,s,p}} \sum_{t\in\text{act}_{n,t,s,p}} \left( \text{VAR\_ACT}_{r,v,t,p,s} \times \text{UC\_ACT}_{uc\_n;LHS,r,t,p,s} \times \left( \text{RS\_FR}_{r,t,s} \right) \right) \\
\sum_{(p,v)\in\text{prvnty}_{n,s,p}} \sum_{t\in\text{act}_{n,t,s,p}} \left( \text{OBJ\_ACOST}_{r,t,p,cur} \right) \quad \text{if } \text{UC\_ATTR}_{r,uc\_n;LHS};\text{ACT};\text{COST} \text{ is given} \\
\sum_{(p,v)\in\text{prvnty}_{n,s,p}} \sum_{t\in\text{act}_{n,t,s,p}} \left( \text{UC\_ACT}_{uc\_n;LHS,r,t,p,s} \right)^{M(t+1)-M(t)-1} \quad \text{if } \text{UC\_ATTR}_{r,uc\_n;LHS};\text{ACT};\text{GROWTH} \text{ is given}
\]
\[ FLO_{\text{GROW}}_{r,j,s: \text{LHS}} = \sum_{(p,c,t) \in \text{rtpcs_varf}, \text{ts}} \sum_{v \in \text{rtp_vintyr}, r, i_p} \left(\text{VAR}_{FLO, r,v,t,j,s} \times UC_{FLO, r,v,t,j,s, n: \text{LHS}}, r,t,p,c,j,s \times \left(\text{RTCS}_{TSFR, r,j,s, t,s}\right)\right) \]

\[

6.4.5 Dynamic user constraints of type (t–1, t)

Mathematical formulation of dynamic user constraints and growth constraints of type (t–1, t)

In the mathematical description of the dynamic user constraints and growth constraints of type (t–1, t), the following placeholders are used for variable terms on the RHS (period t–1):  

\[ \text{ACT\_GROW}_{r, l, p, s, 'RHS'}, \text{FLO\_GROW}_{r, l, p, s, 'RHS'}, \text{IRE\_GROW}_{r, l, p, s, 'RHS'}, \text{COMPRD\_GROW}_{r, l, s, 'RHS'}, \text{COMNET\_GROW}_{r, l, s, 'RHS'}, \text{NCAP\_GROW}_{r, l, p, 'RHS'}, \text{CAP\_GROW}_{r, l, p, 'RHS'}. \]

For the LHS terms (period t), the placeholders are the same ones as defined for the LHS user constraints.

The expressions for the variable terms on the RHS can be written as follows:

\[
\text{ACT\_GROW}_{r, l, s, 'RHS'} = \sum_{(p, v)\in\text{PR}_v} \sum_{t_\in\text{PR}_t} \left( \sum_{\text{OBJ\_ACOST}_{r, l, p, \text{cur}}} \text{if UC\_ATTR}_{r, uc, n, 'RHS', \text{ACT}, \text{COST}} \text{is given} \right. \\
\left. \times \left( \text{VAR\_ACT}_{r, l, j, l, p, s} \times \text{UC\_ACT}_{uc, n, 'RHS', r, l, j, p, s} \times (\text{RS\_FR}_{r, s, l}) \right) \times \left( \text{UC\_ACT}_{uc, n, 'RHS', r, l, j, p, s} \right)^{M(t) - M(t-1)} \text{if UC\_ATTR}_{r, uc, n, 'RHS', 'ACT', \text{GROWTH}} \text{is given} \right)
\]
\[ FLO_{GROW} = \sum_{(p,c,t) \in \text{rtpcs}_\text{var}, t=1:p,c, \in t=1,p} \sum_{v \in \text{rtpvinty}, v=1:p} \left( \sum_{(p,c,t) \in \text{rtpcs}_\text{var}, t=1:p,c, \in t=1,p} \sum_{v \in \text{rtpvinty}, v=1:p} \right) \left( \sum_{(p,c,t) \in \text{rtpcs}_\text{var}, t=1:p,c, \in t=1,p} \sum_{v \in \text{rtpvinty}, v=1:p} \right) \]
COMPRD _GROW
\( r,j-1,s;RHS \)

\[ = \sum_{(c,s) \in \text{varc}_t,j-1,c,s} \left[ \text{VAR _ COMPRD}_{r-1,c,s} \times \text{UC _ COMPRD}_{uc,n,RHS,r,j-1,c,s} \times \left( \text{RTCS _ TSFR}_{r-1,c,s} \right) \times \sum_{r=1}^{M(t)-M(t-1)-1} \left( \text{OBJ _ COMPRD}_{r-1,c,s,ac_cost,cur} \right) \right] \]

COMNET _GROW
\( r,j-1,s;RHS \)

\[ = \sum_{(c,s) \in \text{varc}_t,j-1,c,s} \left[ \text{VAR _ COMNET}_{r-1,c,s} \times \text{UC _ COMNET}_{uc,n,RHS,r,j-1,c,s} \times \left( \text{RTCS _ TSFR}_{r-1,c,s} \right) \times \sum_{r=1}^{M(t)-M(t-1)-1} \left( \text{OBJ _ COMNET}_{r-1,c,s,ac_cost,cur} \right) \right] \]

NCAP _GROW
\( r,j-1;RHS \)

\[ = \left[ \text{VAR _ NCAP}_{r,j-1,p} \times \text{UC _ NCAP}_{uc,n,RHS,r,j-1,p} \times \left( \sum_{r=1}^{M(t)-M(t-1)-1} \left( \text{OBJ _ ICOST}_{r-1,p,cur} \right) \right) \right] \]

\[ - \sum_{p} \left[ \text{OBJ _ ISUB}_{r,j-1,p,cur} \times \text{OBJ _ ITAX}_{r,j-1,p,cur} \times \left( \text{UC _ NCAP}_{uc,n,RHS,r,j-1,p} \right) \right] \]
\[ CAP\_GROW_{r,t-1,\text{RHS}} = \left( \sum_{p} PRC\_CAPACT_{r,p} \times UC\_CAP_{uc\_n,\text{RHS},r-j,1,p} \right) \]
\[ \times \left( \frac{VAR\_CAP_{r,j-1,p} \times UC\_CAP_{uc\_n,\text{RHS},r,j-1,p}}{\left( UC\_CAP_{uc\_n,\text{RHS},r,j-1,p} \right)^{M(t+1)-M(t)-1}} \right) \]
if \( UC\_ATTR_{r,uc\_n,\text{RHS},CAP\_\text{CAPACT}} \) is given
\[ \left( UC\_CAP_{uc\_n,\text{RHS},r,j-1,p} \right)^{M(t+1)-M(t)-1} \] if \( UC\_ATTR_{r,uc\_n,\text{RHS},\text{CAP\_GROWTH}} \) is given
6.4.5.1 Equation: EQ(l)_UCSU / EQE_UCSU

Indices: user constraint (uc_n), period (t)

Related variables: VAR_FLO, VAR_IRE, VAR_NCAP, VAR_CAP, VAR_ACT, VAR_COMPRD, VAR_COMNET

Purpose: The growth constraint of type \((t-1,t)\) EQ(l)_UCSU establishes a constraint between two successive periods \(t-1\) and \(t\). The growth constraint is generated for all periods \(t\) having the UC_RHST constant specified. The constraint is summing over regions \((uc_r\_sum)\) and timeslices \((uc_ts\_sum)\).

Equation:

\[
EQ(l)_UCSU \subseteq \text{uc}_n, t \exists \text{UC}_RHS \subseteq \text{uc}_n, t, bd \wedge \text{uc}_t\_succ \subseteq \text{uc}_n, t, r, s \\
\sum_{uc_r\_sum} \sum_{uc_ts\_sum} \left( ACT \_GROW_{r, j, s, l, H S} + FLO \_GROW_{r, j, s, l, H S} + IRE \_GROW_{r, j, s, l, H S} \right) \\
+ \sum_{uc_r\_sum} \left( NCAP \_GROW_{r, j, l, H S} + CAP \_GROW_{r, j, l, H S} \right)
\]

When control parameter VAR_UC=NO:

\[
\{\leq, =, \geq\}
\]

\[
\text{UC}_RHS \subseteq \text{uc}_n, t, j \\
+ \sum_{uc_r\_sum} \sum_{uc_ts\_sum} \left( ACT \_GROW_{r, j-1, s, H S} + FLO \_GROW_{r, j-1, s, H S} + IRE \_GROW_{r, j-1, s, H S} \right) \\
+ \sum_{uc_r\_sum} \left( NCAP \_GROW_{r, j-1, H S} + CAP \_GROW_{r, j-1, H S} \right)
\]

When control parameter VAR_UC=YES, the user constraint is created as strict equality and the RHS constant UC_RHST is replaced by the variable VAR_UCT. The bounds UC_RHST are then applied to the variable VAR_UCT.
VAR _UCT_{uc_{n,j}}
+
\[ \sum_{ruuc_r\_sum} \sum_{ruuc_b\_sum} \left( \text{ACT\_GROW}_{r,j-1,1,s,'RHS'} + \text{FLO\_GROW}_{r,d-1,1,s,'RHS'} + \text{IRE\_GROW}_{r,j-1,1,s,'RHS'} \right) \]
\[ + \text{COMNET\_GROW}_{r,j-1,1,s,'RHS'} + \text{COMPRD\_GROW}_{r,j-1,1,s,'RHS'} \]

6.4.6 User constraint modifiers

6.4.6.1 Overview

The user constraint facility in TIMES provides a very powerful tool for specifying a large variety of custom user constraints in a TIMES model. Such constraints can refer to practically any combination of individual variables. Moreover, the constraint definitions can be optionally refined by specifying additional modifier attributes that are applied to specific components (variable terms) of the constraints. The modifier attributes available in the current version are listed in Table 25. The note “DYN only” in the table means that the attribute is valid for dynamic constraints only (the constraint is in those cases automatically defined as dynamic if the attribute is used).

As indicated in Table 25, one can easily specify, for example, that the FLO coefficients of the user constraint should apply to the sum of all annual flows in each period, by using the PERIOD attribute. In addition, as cumulative user constraints (summed over periods) are typically almost always meant to be applied also to the sum of the annual flows/activities in each period, the PERIOD modifier is now by default applied to the FLO, ACT, IRE, COMPRD and COMCON components of all cumulative constraints (this can be overridden by the explicit use of the input set uc Ts_sum for the constraint). The specification of various kinds of cumulative constraints is thus possible quite easily.

6.4.6.2 Cost modifiers (COST, TAX, SUB, DELIV)

The cost modifiers are applied to the variable terms by multiplying them with the corresponding cost attribute, or with the sum of multiple cost attributes, if several cost modifiers are specified. The expressions for the $FLO_{t,p,s,LHS}$ term above in section 6.4.2 give a detailed example of how the cost attributes are applied. The cost attributes applied are the following:

- **COST:**  ACT_COST for ACT, FLO_COST for FLO/IRE, NCAP_COST for NCAP, COM_CSTNET for COMNET, and COM_CSTPRD for COMPRD
- **TAX:**  FLO_TAX for FLO/IRE, NCAP_ITAX for NCAP, COM_TAXNET for COMNET, and COM_TAXPRD for COMPRD
- **SUB:**  FLO_SUB for FLO/IRE, NCAP_ISUB for NCAP, COM_SUBNET for COMNET, and COM_SUBPRD for COMPRD
- **DELIV:** FLO_DELIV for FLO/IRE

6.4.6.3 Annuity modifiers (INVCOST, INVTAX, INVSUB)

The annuity modifiers are applied to the variable terms by summing the VAR_NACP variables over all vintage periods $t \leq t$ that have an annual investment payment in period $t$, and multiplying these with the annual cost coefficient. The INVCOST modifier applies the investment cost payments, the INVTAX modifier the tax payments, and the INVSUB modifier the subsidy payments (taken as negative values). By combining several of these modifiers, the payments are summed together.
The CAPACT modifier is applied only to the CAP terms of user constraints, if such exist. The CAP term for each process is multiplied by the PRC_CAPACT parameter of that process when the modifier is used.

### Table 25. User constraint modifier attributes available in TIMES.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COST</td>
<td>Multiple by primary cost attribute (summing together with other cost attributes requested)</td>
</tr>
<tr>
<td>TAX</td>
<td>Multiple by tax attribute (summing together with other cost attributes requested)</td>
</tr>
<tr>
<td>SUB</td>
<td>Multiple by subsidy attribute (summing together with other cost attributes requested)</td>
</tr>
<tr>
<td>DELIV</td>
<td>Multiple by delivery cost attribute (summing together with other cost attributes requested)</td>
</tr>
<tr>
<td>INVCOST</td>
<td>Multiply by investment cost annuities; implies CUMSUM</td>
</tr>
<tr>
<td>INVTAUX</td>
<td>Multiply by investment tax annuities; implies CUMSUM</td>
</tr>
<tr>
<td>INVSUB</td>
<td>Multiply by investment subsidy annuities; implies CUMSUM</td>
</tr>
<tr>
<td>CAPACT</td>
<td>Multiply by PRC_CAPACT</td>
</tr>
<tr>
<td>CAPFLO</td>
<td>Apply coefficients also to any capacity-related flows</td>
</tr>
<tr>
<td>CUMSUM</td>
<td>Sum over all periods up to current or previous period (DYN only)</td>
</tr>
<tr>
<td>EFF</td>
<td>Multiply by COM_IE (UC_COMPRD), divide by COM_IE (UC_COMCON)</td>
</tr>
<tr>
<td>GROWTH</td>
<td>Interpret coefficients as annual change coefficients (DYN only)</td>
</tr>
<tr>
<td>NET</td>
<td>Apply to net production (UC_COMPRD) or consumption (UC_COMCON)</td>
</tr>
<tr>
<td>NEWFLO</td>
<td>Apply coefficient to the flows of the new vintage only</td>
</tr>
<tr>
<td>ONLINE</td>
<td>Apply coefficient to the on-line capacity only (assumed equal to the full capacity if ACT_MINLD has not been defined).</td>
</tr>
<tr>
<td>PERIOD</td>
<td>Multiply by period length (all but NCAP) or COEF_RPTI (NCAP)</td>
</tr>
<tr>
<td>SYNC</td>
<td>Synchronize LHS and RHS sides to refer to the same period</td>
</tr>
<tr>
<td>YES</td>
<td>Declares the constraint to be dynamic, of type (t-1, t)</td>
</tr>
</tbody>
</table>

#### 6.4.6.4 CAPACT modifier

The CAPACT modifier is applied only to the CAP terms of user constraints, if such exist. The CAP term for each process is multiplied by the PRC_CAPACT parameter of that process when the modifier is used.
6.4.6.5 **CAPFLO modifier**

The CAPFLO modifier is applied only to the FLO terms of user constraints, if such exist. When the modifier is used, the FLO term for each process/commodity, which normally includes only the VAR_FLO variables, is augmented by the capacity-related flows of the same commodity, if such exists.

6.4.6.6 **CUMSUM modifier**

The CUMSUM attribute means that the corresponding variable term for any milestone year \( t \) consists of the cumulative sum of the variables in all previous periods up to (and including) the year \( t \). For example, when combined with the INVCOST attribute, the resulting NCAP variable term represents the cumulative sum of capital cost annuities related to all new capacities installed up to the year \( t \), which are paid in year \( t \).

6.4.6.7 **EFF modifier**

The EFF modifier can currently only be applied to COMPRD/COMCON/COMNET, and it causes the variable terms to be either multiplied or divided by the commodity efficiency COM_IE. For COMPRD, the variable terms will refer to the net production after taking into account the commodity efficiency COM_IE. For COMCON, it will refer to the gross consumption before applying the commodity efficiency COM_IE, and with COMNET it will refer to the gross NET production (gross production minus gross consumption).

6.4.6.8 **GROWTH modifier**

The GROWTH modifier used for a variable term causes the user constraint coefficients specified for that term to be interpreted as annual growth/decay coefficients. For example, a coefficient of 1.1 will be interpreted as a growth coefficient corresponding to a 10% annual growth. The final effective coefficient applied to the variable term will be the growth/decay coefficient raised to the power \((M(t)−M(t−1))\) or \((M(t+1)−M(t))\), depending on the dynamic type.

6.4.6.9 **NET modifier**

The NET modifier can only be applied to COMPRD/COMCON. For COMPRD, it causes the variable terms to represent the net amount of production after consumption is subtracted (i.e. gross production in excess of gross consumption). For COMCON, it represents the net consumption in excess of net production (after applying COM_IE), which is normally a non-positive value. Using COMPRD with the NET modifier will thus result in the same variable term as when using COMNET with the EFF modifier.

6.4.6.10 **NEWFLO modifier**

The NEWFLO modifier can only be applied to the ACT, FLO and IRE variable terms. The modifier causes the variable terms to be restricted to the flows or activities of newly installed capacity vintages in the commissioning period only, whenever the process is
vintaged. For non-vintaged processes, the modifier has no effect. Therefore, for making consistent use of the modifier, usually all processes referred to in the variable terms should be vintaged when this modifier is used.

6.4.6.11 ONLINE modifier

The ONLINE modifier can only be used with the CAP variable term. It causes the capacity term to be referring to the on-line capacity instead of the full installed capacity. However, in TIMES, the on-line capacity of a process may differ from the full capacity only when start-ups and shut-downs have been modelled, by defining a minimum stable operating level with the parameter ACT_MINLD.

6.4.6.12 PERIOD modifier

The PERIOD modifier can be used for all other components (variable terms) except for the CAP term. For the ACT, FLO, IRE, COMPXD, COMCON, and COMNET terms, the modifier adds the multiplier D(t), i.e. they are multiplied by the period length. For the NCAP term, the modifier multiplies the new capacity variable for each period by the number of repeated investments in that period.

6.4.6.13 SYNC modifier

The SYNC modifier can be used on the RHS for any component of a user component to signify that the RHS term should refer to the same period as the LHS term. It will also automatically declare the constraint to be dynamic of type (t–1,t), unless uc_t_succ is defined or the GROWTH modifier is used on the LHS side, which both force it to be of type (t,t+1).

6.4.6.14 YES modifier

The only function of the YES modifier is to declare the user constraint to be dynamic. The constraint will be of type (t–1,t), unless uc_t_succ is defined or the GROWTH modifier is used on the LHS side, which forces it to be of type (t,t+1). Using this modifier can thus be useful, if there are no other relevant modifiers to be used on the RHS of the constraint, which would automatically declare the constraint dynamic.

6.4.7 Non-binding user constraints

Non-binding user constraints of any type (introduced for reporting purposes) can be defined in the same way as binding constraints, but using the 'N' lim type when specifying the UC_RHSxxx constant, with any value defined for it (–1 is recommended). Non-binding user constraints can only be defined when user constraint variables are enabled (i.e. when using the option VAR_UC==YES). The levels of the non-binding constraints (i.e. the levels of the slack variables) are reported in the PAR_UCSL reporting attribute (see Section 3.3).
Appendix A
The TIMES Climate Module

1 Introduction

This Appendix contains the updated (November 2010) documentation on the Climate Module option for the TIMES model. It provides a streamlined version of the older version, and contains 5 sections: section 2 contains a detailed description of the theoretical approach taken, section 3 describes the parameters of the climate module, section 4 the variables and section 5 the equations. This version of the documentation does not include the complete formulations for all of the Climate equations (in GAMS form), and neither does it include the full GAMS specifications. However, it should be sufficient to gain a complete understanding of the equations in mathematical form, and should enable the user to define the parameters of the climate module.

2 Mathematical formulation

The Climate Module starts from the global emissions of CO₂, CH₄, and N₂O, as generated by the TIMES global model, and proceeds to compute successively:

- the changes in CO₂, CH₄, and N₂O concentrations via three separate sets of equations,
- the total change (over pre-industrial times) in atmospheric radiative forcing resulting from the three gases plus an exogenously specified additional forcing resulting from other causes (other anthropogenic and/or natural causes, as defined by the user), and
- the temperature changes (over pre-industrial times) in two reservoirs (surface and deep ocean).

The Climate Equations used to perform these calculations were initially adapted from Nordhaus and Boyer (1999), who proposed linear recursive equations for calculating concentrations and temperature changes based on the CO₂ life cycle. These linear equations give results that are good approximations of those obtained from more complex climate models (Drouet et al., 2004; Nordhaus and Boyer, 1999). The non-linear radiative forcing equation used by these authors and in TIMES is the same as the one used in most models. The choice of the Nordhaus and Boyer’s climate equations is motivated by the simplicity of their approach and by the fact that their climate module is well-documented and acceptably accurate. In our implementation, the forcing equation has been replaced by a linear approximation whose values closely approach the exact ones as long as the useful range is carefully selected. This was done in order to keep the entire model linear, and therefore to allow the user to set constraints on forcing and on temperature as well as on concentrations and on emissions.
Rigorously, the concentration and forcing equations used in the climate module are applicable only to CO2 emissions, since the concentration equations simulate the carbon cycle. In order to model other GHGs, one way is to use these same equations, while replacing CO2 emissions by CO2-equivalent emissions of any number of gases endogenous to the model. However, a more detailed and generally preferable approach is to model separately the life cycle of each endogenous emission separately, and this is the approach used in TIMES. The additional forcing due to the remaining (non endogenous) emissions, is accounted for via an exogenous forcing quantity directly defined by the user.

We now describe the mathematical equations used at each of the three steps of the climate module.

2.1 Concentrations (accumulation of CO2, CH4, N2O)

a) CO2 accumulation is represented as the linear three-reservoir model below\(^{45}\): the atmosphere, the quickly mixing upper ocean + biosphere, and the deep ocean. CO2 flows in both directions between adjacent reservoirs. The 3-reservoir model is represented by the following 3 equations when the step of the recursion is equal to one year:

\[
\begin{align*}
M_{\text{atm}}(y) &= E(y) + (1 - \phi_{\text{atm-up}}) M_{\text{atm}}(y-1) + \phi_{\text{up-atm}} M_{\text{up}}(y-1) \\
M_{\text{up}}(y) &= (1 - \phi_{\text{up-atm}} - \phi_{\text{up-lo}}) M_{\text{up}}(y-1) + \phi_{\text{atm-up}} M_{\text{atm}}(y-1) + \phi_{\text{lo-up}} M_{\text{lo}}(y-1) \\
M_{\text{lo}}(y) &= (1 - \phi_{\text{lo-up}}) M_{\text{lo}}(y-1) + \phi_{\text{up-lo}} M_{\text{up}}(y-1)
\end{align*}
\]

with

\begin{itemize}
  \item \(M_{\text{atm}}(y), M_{\text{up}}(y), M_{\text{lo}}(y)\): masses of CO2 in atmosphere, in a quickly mixing reservoir representing the upper level of the ocean and the biosphere, and in deep oceans (GtC), respectively, in year \(y\) (GtC)
  \item \(E(y-1)\) = CO2 emissions in previous year (GtC)
  \item \(\phi_{ij}\), transport rate from reservoir \(i\) to reservoir \(j\) (\(i, j = \text{atm, up, lo}\)) from year \(y-1\) to \(y\)
\end{itemize}

b) CH4 accumulation is represented by a so-called single-box model in which the atmospheric methane concentration obeys the following equations assuming a constant annual decay rate of the anthropogenic concentrations \(\Phi_{\text{CH4}}\) (whereas the natural concentration is assumed in equilibrium):

\[
\begin{align*}
CH4_{\text{atm}}(y) &= (1 - \Phi_{\text{CH4}}) \cdot CH4_{\text{atm}}(y-1) + EA_{\text{CH4}}(y) \\
CH4_{\text{up}}(y) &= CH4_{\text{up}}(y-1) \\
CH4_{\text{tot}}(y) &= CH4_{\text{atm}}(y) + CH4_{\text{up}}(y)
\end{align*}
\]

where

\(^{45}\)There exists another well-known representation of CO2 accumulation equations, using a five-box model.
- CH4_{atm}, CH4_{up}, and EA_{CH4} are respectively: the atmospheric concentration, the natural concentration\(^{46}\) (both expressed in Mt), and the anthropogenic emission of CH4 (expressed in Mt/yr). EA_{CH4} is generated within the model, but CH4_{up} is fully exogenous (see values for CH4-UP and CH4-ATM in Table A-2). All quantities are indexed by year.
- d_{CH4} = 2.84 (the density of CH4, expressed in Mt/ppbv) is then used to convert concentration in Mt into ppbv.
- 1 - \Phi_{CH4} is the one-year retention rate of CH4 in the atmosphere, see Table A-1.

c) N2O accumulation is also represented by a single-box model in which the atmospheric N2O concentration obeys the following equations:

\[
\begin{align*}
N2O_{atm}(y) &= (1 - \Phi_{N2O}) \cdot N2O_{atm}(y-1) + EA_{N2O}(y) \quad (1b) \\
N2O_{up}(y) &= N2O_{up}(y-1) \quad (2b) \\
N2O_{io}(y) &= N2O_{atm}(y) + N2O_{up}(y) \quad (2c)
\end{align*}
\]

where
- N2O_{atm}, N2O_{up}, and EA_{N2O}, are respectively: the atmospheric concentration, the natural concentration (both expressed in Mt), and the anthropogenic emission of N2O (expressed in Mt/yr). EA_{N2O} is generated within the model, but N2O_{up} is fully exogenous (see values for N2O-UP and N2O-ATM in Table A-2). All quantities are indexed by year.
- d_{N2O} = 7.81 (the density of N2O, expressed in Mt/ppbv) is then used to convert concentration in Mt to ppbv units.
- 1 - \Phi_{N2O} is the one-year retention rate of N2O in the atmosphere, see table A-1.

Note: For both CH4 and N2O, the total atmospheric concentrations (UP+ATM) are used in the forcing expressions (see below) and are reported in the results.

2.2 Radiative forcing

We assume, as is routinely done in atmospheric science, that the atmospheric radiative forcing caused by the various gases are additive (IPCC, 2007). Thus:

\[
\Delta F(y) = \Delta F_{CO2}(y) + \Delta F_{CH4}(y) + \Delta F_{N2O}(y) + EXOFOR(y) \quad (3)
\]

We now explain these four terms.

a) The relationship between CO2 accumulation and increased radiative forcing, \Delta F_{CO2}(y), is derived from empirical measurements and climate models (IPCC 2007).

46 Note that the subscripts atm and up, which for the CO2 equations referred to the atmosphere and upper reservoirs, have been reused for the CH4 and N2O equations to stand for anthropogenic and natural concentrations.
\[ \Delta F_{CO2}(y) = \gamma \times \frac{\ln (M_{atm}(y)/M_0)}{\ln 2} \]  

(4a)

where:
- \( M_0 \) (i.e. CO2ATM_PRE_IND) is the pre-industrial (circa 1750) reference atmospheric concentration of CO2 = 596.4 GtC
- \( \gamma \) is the radiative forcing sensitivity to atmospheric CO2 concentration doubling = 3.7 W/m²

b) The radiative forcing due to atmospheric CH4 is given by the following expression (IPCC, 2001)

\[ \Delta F_{CH4}(y) = 0.036 \cdot \left( \sqrt{CH4_y} - \sqrt{CH4_0} \right) - \left[ f(CH4_y, N2O_0) - f(CH4_0, N2O_0) \right] \]  

(4b)

c) The radiative forcing due to atmospheric N2O is given by the following expression (IPCC, 2001)

\[ \Delta F_{N2O}(y) = 0.12 \cdot \left( \sqrt{N2O_y} - \sqrt{N2O_0} \right) - \left[ f(CH4_0, N2O_y) - f(CH4_0, N2O_0) \right] \]  

(4c)

where:

\[ f(x, y) = 0.47 \cdot \ln \left[ 1 + 2.01 \cdot 10^{-5} \cdot (xy)^{0.75} + 5.31 \cdot 10^{-15} \cdot x(xy)^{1.52} \right] \]  

(4d)

Note that the \( f(x,y) \) function, which quantifies the cross-effects on forcing of the presence in the atmosphere of both gases (CH4 and N2O), is not quite symmetrical in the two gases. As usual, the 0 subscript indicates the pre-industrial times (1750)

d) \( EXOFOR(y) \) is the increase in total radiative forcing at period \( t \) relative to pre-industrial level due to GHGs that are not represented explicitly in the model. Units = W/m². In Nordhaus and Boyer (1999), only emissions of CO2 were explicitly modeled, and therefore O(y) accounted for all other GHG’s. In TIMES, N2O and CH4 are fully accounted for, but some other substances are not (e.g. CFC’s, aerosols, ozone, etc.). Therefore, our values for \( EXOFOR(y) \) will differ from those in Nordhaus and Boyer. It is the modeler’s responsibility to include in the calculation of \( EXOFOR(y) \) only the forcings from those gases and other causes that are not modeled. Table A-3 shows a possible trajectory for EXOFOR.

The parameterization of the three forcing equations (4a, 4b, 4c) is not controversial and relies on the results reported by Working Group I in the IPCC. IPCC (2001, Table 6.2, p.358) provides a value of 3.7 for \( \gamma \), smaller than the one used by Nordhaus and Boyer (\( \gamma = 4.1 \)). We have adopted this lower value of 3.7 W/m² as default in TIMES. Users are free to experiment with other values of the \( \gamma \) parameter. The same reference provides the entire expressions for all three forcing equations.
2.3 Linear approximations

In TIMES, each of the three forcing expressions is replaced by a linear approximation, in order to preserve linearity of the entire model. All three forcing expressions \((4a, 4b, 4c)\) happen to be concave functions. Therefore, two linear approximations are obvious candidates. The first one is an approximation from below, consisting of the chord of the graph between two selected points. The second one has the same slope as the chord and is tangent to the graph, thus approximating the function from above. The final approximation is taken to be the arithmetic average of the two approximations. These linear expressions are easily derived once a range of interest is defined by the user.

As an example, we derive below the linear approximation for the CO2 forcing expression. The other approximations are obtained in a similar manner, and the parameters of the linear approximations are shown in the next section.

**Linear approximation for the CO2 forcing expression:**

First, an interval of interest for the concentration \(M\) must be selected by the user. The interval should be wide enough to accommodate the anticipated values of the concentrations, but not so wide as to make the approximation inaccurate. We denote the interval \((M_1,M_2)\).

Next, the linear forcing equation is taken as the half sum of two linear expressions, which respectively underestimate and overestimate the exact forcing value. The underestimate consists of the chord of the logarithmic curve, whereas the overestimate consists of the tangent to the logarithmic curve that is parallel to the chord.

By denoting the pre-industrial concentration level as \(M_0\), the general formulas for the two estimates are as follows:

\[
\text{Overestimate: } F_1(M) = \frac{\gamma}{\ln 2} \left[ \ln\left(\frac{\gamma}{\text{slope} \cdot \ln(2) \cdot M_0}\right) - 1 \right] + \text{slope} \cdot M \tag{5}
\]

\[
\text{Underestimate: } F_2(M) = \gamma \cdot \ln(M_1 / M_0) / \ln 2 + \text{slope} \cdot (M - M_1) \tag{6}
\]

\[
\text{Final approximation: } \quad F_3(M) = \frac{F_1(M) + F_2(M)}{2} \tag{7}
\]

\[
\text{where: } \quad \text{slope} = \gamma \cdot \frac{\ln(M_2 / M_1) / \ln 2}{(M_2 - M_1)}
\]

The linearized forcing expression implemented in TIMES is the average of the two linear estimates.
2.4 Temperature increase

In the TIMES Climate Module as in many other integrated models, climate change is represented by the global mean surface temperature. The idea behind the two-reservoir model is that a higher radiative forcing warms the atmospheric layer, which then quickly warms the upper ocean. In this model, the atmosphere and upper ocean form a single layer, which slowly warms the second layer consisting of the deep ocean.

\[
\Delta T_{\text{up}}(y) = \Delta T_{\text{up}}(y-1) + \sigma_1 \{ F(y) - \lambda \Delta T_{\text{up}}(y-1) - \sigma_2 [\Delta T_{\text{up}}(y-1) - \Delta T_{\text{low}}(y-1)] \} \tag{8}
\]

\[
\Delta T_{\text{low}}(y) = \Delta T_{\text{low}}(y-1) + \sigma_3 [\Delta T_{\text{up}}(y-1) - \Delta T_{\text{low}}(y-1)] \tag{9}
\]

with

- \( \Delta T_{\text{up}} \) = globally averaged surface temperature increase above pre-industrial level,
- \( \Delta T_{\text{low}} \) = deep-ocean temperature increase above pre-industrial level,
- \( \sigma_1 \) = 1-year speed of adjustment parameter for atmospheric temperature (also known as the lag parameter),
- \( \sigma_2 \) = coefficient of heat loss from atmosphere to deep oceans,
- \( \sigma_3 \) = 1-year coefficient of heat gain by deep oceans,
- \( \lambda \) = feedback parameter (climatic retroaction). It is customary to write \( \lambda = \gamma C_s \), \( C_s \) being the climate sensitivity parameter, defined as the change in equilibrium atmospheric temperature induced by a doubling of CO\(_2\) concentration.

Remark: in contrast with most other parameters, the value of \( C_s \) is highly uncertain, with a possible range of values from 1\(^\circ\)C to 10\(^\circ\)C. This parameter is therefore a prime candidate for sensitivity analysis, or for treatment by probabilistic methods such as stochastic programming. In Table A-2, a best estimate value of 2.9 \(^\circ\)C is shown, as per IPCC (2001, 2007).

In the next section we describe all the input parameters required to define the climate equations and those needed to define climate constraints. With few exceptions (such as the densities of the gases), all parameters are modifiable by the user, should the need arise. We also provide Table A-2 summarizing the default values of the parameters.
3 Switches and Parameters

3.1 Activating the Climate Module

The Climate Module (CLI) extension of TIMES can be activated and employed by using the Parameters and Switches described in this chapter.

Besides the basic input data parameters described in Table A-1, the user also has full control over the CLI component being activated by means of the $SET CLI YES switch. This switch is provided by the data handling system when the user indicates that the CLI option is to be included:

$SET CLI YES

3.2 Calibration

The calibration of the Climate Module to historical values is an important aspect of using the module. The mass balance and temperature equations can be calibrated for the first period by using three alternative calibration years B(1)–1, m(1)–1, and m(1). Whenever D(1)=1, the first two alternatives are equal. The default calibrating year is m(1)–1. The alternative calibration years can be activated by using one of the following two settings in the run-file:

$SET CM_CALIB B ! Calibrate at the end of B(1)–1
$SET CM_CALIB M ! Calibrate at the end of m(1)

3.3 Controlling the years considered beyond EOH

The Climate Equations will be calculated beyond EOH at each of the years for which either a user-defined emission target or a temperature or concentration bound is specified. The years considered thus span between the EOH and the last year for which a CM_MAXC is specified.

In addition, by default any Climate Equations beyond EOH will be calculated only at each year having a year value divisible by 20. This default year resolution can be changed by using the Climate Module constant 'BEOHMOD'. However, note that the years available in the model extend by default to 2200 only, and therefore one may need to adjust the year-span e.g. to 2300 by using the following switch:

$SET EOTIME 2300

The reporting years for the climate variables are the same as the calculation years.
3.4 Input parameters

Like all other aspects of TIMES, the user defines the Climate Module components of the energy system by means of input parameters, which are described in this section. Table A-1 below describes the User Input Parameters that are associated with the Climate Module option.

Table A-1. Definition of Climate Module user input parameters.

### Input Parameter (Indexes) | Units & Defaults | Description
--- | --- | ---
none | constant term (FX) of the linear forcing function N2O-PPB: multiplier (N) for the N2O concentration and constant term (FX) of the linear forcing function

| CM_MAXC (y, cm_var) | Default: none | Maximum level of climate indicator cm_var in year y.
| CO2-GtC: CO2 emissions in GtC |
| CH4-Mt: CH4 emissions in Mt |
| N2O-Mt: N2O emissions in Mt |
| CO2-ATM: atm. CO2 concentration / pre-industrial ratio |
| CO2-PPM: atm. CO2 concentration in ppm |
| CH4-PPB: atm. CH4 concentration in ppb |
| N2O-PPB: atm. N2O concentration in ppb |
| DELTA-ATM: atmospheric temperature change, in °C |
| FORCING: total radiative forcing, in W/m² |

| CM_MAXCO2C (y) | Unit: GtC | Maximum level of CO2 concentration in GtC. |

#### 3.4.1 Mapping of regional emissions to global emissions

Conversion from regional emissions to global emissions must be done by using the CM_GHGMAP(r,c,cg) parameter, in adequate units. The labels for the global emissions cg are 'CO2-GtC', 'CH4-Mt' and 'N2O-Mt'. The parameter IRE_CCVT(r,c,r,cg) can alternatively be also used, if CM_GHGMAP is not available.

Assuming here that the total regional emissions are represented by the commodities TOTCO2, TOTCH4 and TOTN2O, and are measured in kt, as is the case in TIAM models for instance, the mapping and conversion would be the following:

\[
\begin{align*}
\text{CM_GHGMAP}(R, 'TOTCH4', 'CH4-Mt') &= 1 \times 10^{-3}; \\
\text{CM_GHGMAP}(R, 'TOTN2O', 'N2O-Mt') &= 1 \times 10^{-3}; \\
\text{CM_GHGMAP}(R, 'TOTCO2', 'CO2-GtC') &= 2.727272 \times 10^{-7}
\end{align*}
\]

#### 3.4.2 Deterministic input parameters for CO₂

- **CM_CONST(\{PHI_AT_UP, PHI_UP_AT, PHI_UP_LO, PHI_LO_UP\})** (also denoted \(\phi_{atm-up}, \phi_{up-atm}, \) etc, in the equations of section 2): annual CO₂ flow coefficients between the three reservoirs (AT=Atmosphere, UP=Upper ocean layer, LO=Deep ocean layer). These are time-independent coefficients. Units: none
- **CM_HISTOR Y(y, \{CO2-ATM, CO2-UP, CO2-LO\})**: Values at the end of the calibration year y of the masses of CO₂ in the atmosphere, the upper ocean layer, and the deep ocean layer, respectively. Note that these values are time-indexed so that the model generator can pick up the correct value according to the calibration year chosen by the user. Units: GtC, Mt(CH4), Mt(N2O).
- **CM_CONST(CO2-PREIND)**: Pre-industrial atmospheric mass of CO2. Units = GtC
3.4.3 Parameters for the linear CO\textsubscript{2} forcing approximation

CM\_LINFOR(datayear,item,lim): lower and upper limit for the concentration of CO\textsubscript{2} in atmosphere, used in the approximation of the radiative forcing equation for CO\textsubscript{2} (see section 2.2 above). \textit{item} may be equal to CO2-ATM (in which case the limit is expressed as a ratio of concentration over pre-industrial concentration), or to CO2-PPM (in which case the limit is expressed in ppm of CO2-equivalent). The index \textit{lim} is either equal to LO or to UP, depending on whether the lower or the upper limit of the range is being specified. For example, the following specifications may be used to select a range from 375 to 550 ppm for the approximation at year 2020:

- CM\_LINFOR('2020', 'CO2-PPM', 'LO') = 375;
- CM\_LINFOR('2020', 'CO2-PPM', 'UP') = 550;

Note that the values of LINFOR are systematically interpolated. The range can also be specified in a time-dependent manner taking into account the gradual increase in the expected range of possible concentration levels over time. That would further improve the accuracy of the linearization. For example, for 2005 the range could be specified to consist of only a single value, because the actual concentration in 2005 is well-known.

3.4.4 Parameters for modeling the concentrations and forcings of other greenhouse gases

\textbf{Historical base year values of natural (UP) and anthropogenic (ATM) concentrations} (in Mt), needed at for the base year of the model (default 2005):

\begin{align*}
\text{CM\_HISTORY('2005', 'CH4-UP')} &= 1988; \\
\text{CM\_HISTORY('2005', 'CH4-ATM')} &= 3067; \\
\text{CM\_HISTORY('2005', 'N2O-UP')} &= 2109; \\
\text{CM\_HISTORY('2005', 'N2O-ATM')} &= 390;
\end{align*}

In the results the total concentrations (UP+ATM) are reported for both CH\textsubscript{4} and N\textsubscript{2}O.

\textbf{Annual exponential decay of concentrations (PHI-xxx = 1/Life)}:

\begin{align*}
\text{CM\_CONST('PHI-CH4')} &= 0.09158; \\
\text{CM\_CONST('PHI-N2O')} &= 0.008803;
\end{align*}

Here \(\Phi_{\text{CH4}}\), \(\Phi_{\text{N2O}}\), are the one-year decay rates for methane and N\textsubscript{2}O respectively.

\textbf{Parameters for the linear CH\textsubscript{4} and N\textsubscript{2}O forcing approximations:}

Note that for specifying the linear forcing functions for CH\textsubscript{4} and N\textsubscript{2}O, the LO/UP bounds cannot be used, but the slope ('N') and constant ('FX') of the forcing functions must be directly defined by the user. Example:

\begin{align*}
\text{CM\_LINFOR('2010', 'CH4-PPB', 'N')} &= 0.000340;
\end{align*}
Parameter for the exogenous radiative forcing from non-modeled gases in each year from initial year: CM_EXOFOR(y)

Units: Watts/m².

3.4.5 Parameters for the temperature equations

- CM_CONST(SIGMA1) (also denoted σ1): speed of adjustment parameter for atmospheric temperature. 1/σ1 represents the thermal capacity of the atmospheric + upper ocean layer (W-yr/m²°C). Note however that when SIGMA1 is assumed stochastic, its multiple values are specified via the generic S_CM_CONST parameter described below.
- CM_CONST(SIGMA2) (also denoted σ2): ratio of the thermal capacity of the deep oceans to the transfer rate from shallow to deep ocean (W/m²°C).
- CM_CONST(SIGMA3) (also denoted σ3): 1/σ3 is the transfer rate (per year) from the upper level of the ocean to the deep ocean (yr⁻¹).
- CM_CONST(GAMMA) (also denoted γ): radiative forcing sensitivity to a doubling of the atmospheric CO₂ concentration. Units: Watts/m².
- CM_CONST(CS): Cₛ, the temperature sensitivity to a doubling of the CO₂ concentration (ºC).
- CM_CONST(LAMBDA) (also denoted λ): a feedback parameter, representing the equilibrium impact of CO₂ concentrations doubling on climate. λ = γ / Cₛ. Note however that when Cₛ is assumed stochastic, its multiple values are specified via the generic S_CM_CONST parameter described below. If all three of λ, γ and Cₛ are specified, the user-specified λ is overridden by the derived value γ / Cₛ.
- CM_HISTORY(y,{DELTA_ATM, DELTA_LOW}): values at the end of the calibration year y of the temperature changes (wrt to pre-industrial time) in atmosphere and deep layer, respectively. Units: ºC

3.4.6 Upper bounds on climate variables

The following parameters are needed if constraints on some climate variables are desired. In TIMES, several climate upper bounds may be specified at any year. These upper bounds are specified via the single generic parameter CM_MAXC(datayear,item), where datayear is the year at which the bound applies, and item may be any of the following nine choices:

- CO2-ATM: for bounding the ratio of GHG concentration to the preindustrial concentration (where the pre-industrial concentration is defined by CO2-PREIND);
- CO2-PPM: for bounding the CO2 concentration expressed in ppm;
- CH4_PPB: for bounding the CH4 concentration expressed in ppbv;
- N2O-PPB: for bounding the N2O concentration expressed in ppbv;
• FORCING: for bounding the total atmospheric radiative forcing expressed in W/m². (If this bound or the next one on temperature is used, the linearized forcing equation is used rather than the exact forcing equation);
• DELTA-ATM: for bounding the change in global atmospheric temperature over pre-industrial temperature, expressed in °C;
• CO2-GTC: for bounding the global CO2 emissions expressed in GtC;
• CH4-MT: for bounding the global CH4 emissions expressed in Mt;
• N2O-MT: for bounding the global N2O emissions expressed in Mt.

In addition, the user can also bound the CO2 concentration expressed in GtC, by using CM_MAXCO2C.

3.4.7 Incorporating climate variables in UC constraints

When using the Climate Module extension, one can also refer to the climate variables in user constraints. The UC attribute for that purpose is the following:

\[
\text{UC\_CLI(uc\_n, side, reg, y, item)}
\]

This parameter can be used to define climate variable coefficients in any period-wise user constraints. The UC\_GRPTYPE (to be used in UC\_ATTR) for this parameter is 'CLI'. The item index can be any of the following climate variables:

- CO2-GTC - total global CO2 emissions (or CO2-eq. GHGs)
- CO2-ATM - CO2 concentration in the atmosphere
- CO2-UP - CO2 concentration in the biosphere/upper ocean
- CO2-LO - CO2 concentration in the deep ocean layer
- FORCING - radiative forcing
- DELTA-ATM - atmospheric temperature
- DELTA-LO - deep oceanic temperature

The attribute can be used for defining custom relationships by each region, between any of the climate variables and e.g. process flows, activities or capacities, or total commodity flows. However, if used in a global constraint, one should normally define the UC\_CLI attribute only for one region (e.g. GLB).

3.4.8 Random climate parameters (refer to documentation on stochastic TIMES)

If the stochastic programming version of TIMES is used, several climate parameters may be assumed random. These fall into two categories: the upper bounds on climate quantities discussed in the previous section, and the two climate coefficients, Cs and SIGMA1.

Regarding the random upper bounds, their multiple values are specified via the stochastic version of the CM_MAX parameter, namely S_CM_MAX(datayear,item,stage,sow), where in addition to datayear and item already explained, stage refers to the stage of the event tree and sow refers to the state-of-the-world. Note that this single generic parameter will be specified as many times as there are
stages and sow’s in the stochastic event tree. If this parameter is specified, the corresponding values of the deterministic parameter CM_MAX are superseded.

Regarding the two random coefficients, their multiple values are then declared via the single generic parameter S_CM_CONST(item,stage,sow), where item may be equal to CS or to SIGMA1, stage is the stage number, and sow is the state-of-the-world. Note that this single generic parameter will be specified as many times as there are stages and sow’s in the stochastic event tree. If this parameter is specified, the corresponding values of the deterministic parameter (LAMBDA and/or SIGMA1) are superseded.

The reader is referred to Chapter 8 of Part I and the documentation of the stochastic programming version of TIMES for the precise meaning of the stage and sow concepts.

Remark: in addition to the possible values of the random parameters, the user must specify the probabilities attached to each sow. This is also explained in the documentation on stochastic TIMES.

### 3.4.9 Parameters for extending the Climate Module equations beyond EOH

The main purpose of extending the climate equations beyond EOH is to be able to set climate targets beyond EOH. This is particularly useful for DeltaT targets, because there is a considerable time lag between the decline of emissions and the peak of DeltaT.

The extended climate equations must be explicitly activated by the user. The activation can be done by specifying any non-negative value for the new Climate Module constant CM_CONST('EXT-EOH'). Different values of the constant will have the following meaning:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1 (default)</td>
<td>The feature is deactivated.</td>
</tr>
<tr>
<td>0</td>
<td>In this case 'EXT-EOH' will be automatically adjusted to $E(M)$, where $M$ is the last model year $m$ for which the end-year $E(m)$ is specified. The adjusted parameter will then have the same meaning as in the case $EXT-EOH &gt; 0$ below.</td>
</tr>
<tr>
<td>&gt;0</td>
<td>The emissions at EOH will remain constant at the endogenous value in EOH=$E(T)$ (where $T$=last milestone year) until the year $MAX(EXT-EOH, EOH)$, and then develop linearly from that value to the first user-defined emission value in a subsequent year.</td>
</tr>
</tbody>
</table>

The setting $EXT-EOH=0$ may be useful for ensuring that any user-defined target values for the emissions will only be taken into account beyond the last model year, even in model runs where a truncated model horizon is used. In such case, when $EXT-EOH=0$ is used, the emissions are assumed to remain constant between the truncated EOH and the end of the full model horizon.

A positive value $EXT-EOH=y \leq EOH$ means that a linear development of emissions towards the first user-defined value is requested to start immediately at the EOH, regardless of the model horizon being truncated or not. Finally, a positive value $EXT-EOH=y > EOH$ can be useful if the user wishes the emissions to remain constant at the EOH value until a predefined year $y > EOH$, before turning into the linear development towards the first user-defined value.
**Warning:** If \(0 < \text{EXT-EOH} < \text{E(M)} = \text{MAX}\_m(\text{E}(m))\), any user-defined global emission bounds for CO2-GTC, CH4-MT or N2O-MT, which may be inadvertently specified at years between \(\text{MAX}(\text{EXT-EOH}, \text{EOH})\) and \(\text{E(M)}\), will also be taken into account as target values for the emission trajectories.

The global greenhouse gas emissions that can be considered by the extended climate equations are the three main input emissions to the Climate Module:

- **CO2-GTC** Global CO2 emissions, expressed in GtC
- **CH4-MT** Global CH4 emissions, expressed in Mt
- **N2O-MT** Global N2O emissions, expressed in Mt

The user can specify target emission values for these emissions at any year(s) beyond EOH. For simplicity, the target emission values are specified by using the \text{CM\_MAXC} parameter, which is normally used for specifying upper bounds for the global emissions, as well as for the temperature and concentrations.

Starting from the year \(B = \text{MAX}(\text{EOH}, \text{EXT-EOH})\), the emissions will be assumed to develop linearly from the value at EOH to the first user-specified value beyond \(B\). If no target values are specified, the emissions will be assumed to remain constant at the EOH value. If several successive values are specified, the emissions will develop linearly also between the successive target values.

Bounds on the global atmospheric temperature, forcing or GHG concentrations can be specified at any years beyond the EOH, in the normal way. In addition, exogenous forcing can be specified and is interpolated beyond EOH.

The Climate Equations will be calculated beyond EOH at each of the years for which either a user-defined emission target or a temperature or concentration bound is specified. The years considered thus span between the EOH and the last year for which a CM\_MAXC is specified. However, as described above, any emission bounds between EOH and MAX(EOH,EXT-EOH) will be ignored.

In addition, by default the Climate Equations will be calculated also at each year having a year value divisible by 20. This default year resolution can be changed by using the new Climate Module constant \text{BEOHMOD}'. Accordingly, if the user wishes the Climate Equations to be calculated at 10 years’ intervals (in addition to the CM\_MAXC years) she can specify the following parameter:

```
PARAMETER CM\_CONST / BEOHMOD 10 /;
```

The **reporting years** for the climate variables are the same as the calculation years.

### 3.5 Internal parameters

- **\text{CM\_PPM}_{cm\_var}**: The densities of the greenhouse gases are hard coded in TIMES (via the internal parameter), with the following values:
  - density of \text{CH4} : 2.84 Mt / ppbv
  - density of \text{N2O} : 7.81 Mt / ppbv
  - density of \text{CO2} : 2.13 Gt / ppm.
• **CM PHI**<sub>cm_var,t,i,j</sub>: The transition matrix for climate indicator cm_var between reservoirs i and j and successive years t–1 and t;
• **CM AA**<sub>cm_var,t,i,j</sub>: The transition matrix for climate indicator cm_var between reservoirs i and j and between the milestone years of periods t–1 and t;
• **CM BB**<sub>cm_var,t,i,j</sub>: The transition matrix for climate indicator cm_var from emissions in period t to reservoir contents in the same period;
• **CM CC**<sub>cm_var,t,i,j</sub>: The transition matrix for climate indicator cm_var from emissions in period t–1 to reservoir contents in the period t.

### 3.6 Reporting parameters

There are two reporting parameters, CM_RESULT and CM_MAXC_M, which contain the results on the levels of the climate variables (or reporting quantities) and the dual values of the constraints defined by using CM_MAXC.

CM_RESULT is indexed by year y and result type {e.g. CO2-ATM, CO2-PPM, FORCING, DELTA-ATM, DELTA_LO}. The values represent the quantities at the end of year y. The reporting years y include the milestone years plus any years beyond m(T) that either have some CM_MAXC bound defined or are modulo(BEOHMOD).

- CO2-GtC(y): the total global CO2 emissions at the end of year y.
- CO2-ATM(y): the value of the atmospheric mass of CO2-equivalent at the end of year y, obtained directly from the variable VAR_CLIBOX('CO2-ATM',y).
- CO2-PPM(y): the value of the atmospheric concentration of CO2-equivalent at the end of year y.
- FORCING(y): forcing value at end of year y, calculated using the linearized forcing functions as defined by the user.
- FORC+TOT(y): exact forcing value at end of year y, calculated using the logarithmic forcing equation defined in section 2.2 and the CO2-ATM(y) value.
- DELTA_ATM(y): exact atmospheric temperature value at end of year y, calculated using the forcing FORC+TOT(y).
- DELTA_LOW(y): exact lower ocean temperature value at end of year y, calculated using the forcing FORC+TOT(y).

CM_MAXC_M is indexed by year y and constraint type. The values are reported for each of the EQ_CLITOT and EQ_CLIMAX equations. The values represent directly the dual values of these constraints at year y.
3.7 Default values of the climate parameters

Table A-2 shows the default values of all parameters of the Climate Module except exogenous forcing. All defaults may be modified by the user.

- CS and SIGMA1 may be assumed random, in which case the default values are not used. The user must specify their values explicitly using the appropriate parameter names described earlier.
- The parameters highlighted blue are upper bounds on five climate variables (in this example, they are set high enough to be inoperative).
- The three parameters highlighted pink concern the extension of emissions beyond EOH, as described in the separate note on this subject.

Table A-3 shows an example of specification of the EXOFORCING time series.

4 Variables

The variables that are used in the Climate Module in TIMES are presented in Table A-4 below. The climate indicators represented in the Climate Module are grouped according to the following internal sets, which are referred to in the GAMS formulation, presented in Section 5:

- **cm_var**: the set of all climate indicators
- **cm_tkind**: aggregate total indicators (CO2-GtC, CH4-Mt, N2O-Mt, FORCING)
- **cm_emis**: emission indicators (CO2-GtC, CH4-Mt, N2O-Mt)
- **cm_boxmap**\(tkind,cm\_var,cm\_box\): mapping between aggregate indicators \(tkind\), reservoir indicators \(cm\_var\), and corresponding box labels (ATM/UP/LO);
- **cm_atmap**\(tkind,cm\_var\): mapping between aggregate indicators \(tkind\) and the corresponding boundable atmospheric indicators (CO2-PPM/CH4-PPM/N2O-PPM/DELTA_ATM);
- **cm_atbox**\(tkind,cm\_box\): mapping between mapping between aggregate emission indicators \(tkind\) and the corresponding reservoirs that comprise the atmospheric concentration part; contains the pairs \{(CO2-GtC,ATM), (CH4-Mt,ATM),(CH4-Mt,UP),(N2O-Mt,ATM),(N2O-Mt,UP) \}

<table>
<thead>
<tr>
<th>Variable (Indexes)</th>
<th>Variable Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VAR_CLITOT (cm_var,y)</td>
<td>Represents the total amount of climate indicator (cm_var) in year (y), where (cm_var) is one of {CO2-GtC, CH4-Mt, N2O-Mt, FORCING}.</td>
</tr>
<tr>
<td>VAR_CLIBOX (cm_var,y)</td>
<td>Represents the amount of reservoir indicator (cm_var) in a single reservoir/box in year (y), where (cm_var) is one of {CO2-ATM, CO2-UP, CO2-LO, CH4-ATM, CH4-UP, N2O-ATM, N2O-UP, DELTA-ATM, DELTA-LO}.</td>
</tr>
</tbody>
</table>
4.1 VAR_CLITOT(cm_var,y)

**Description:** The total amount of aggregate climate indicator in year y.

**Purpose and Occurrence:** This variable tracks the total amount of an aggregate climate indicator by period. This variable is generated for each main emission type of the Climate Module as well as for the total forcing from all greenhouse gas concentrations.

**Units:** GtC (for CO2 emissions), Mt (for CH4 and N2O emissions), or W/m² (for total radiative forcing).

**Bounds:** This variable can be directly bounded with the CM_MAXC attribute.

4.2 VAR_CLIBOX(cm_var,y)

**Description:** The amount of climate indicator in a reservoir.

**Purpose and Occurrence:** This variable tracks the amount of reservoir-specific climate indicator by period. This variable is generated for each of the reservoirs for each of the aggregate indicators: ATM/UP/LO for CO2 emissions, ATM/UP for CH4 and N2O emissions, and ATM/LO for FORCING (connected to the temperature reservoirs).

**Units:** GtC (for CO2 emissions), Mt (for CH4 and N2O emissions), or °C (for temperature reservoirs).

**Bounds:** Only the total atmospheric amounts can be bounded with the CM_MAXC attribute (CO2-ATM, CO2-PPM, CH4-PPB, N2O-PPB, DELTA-ATM).
5 Equations

There are three blocks of definitional equations: the first block of equations calculates the global emissions of GHG (either all in CO₂ eq., or separately for CO₂, CH₄ and N₂O) as well as the total (linearized) radiative forcing, the next block calculates the concentrations of the greenhouse gases in the reservoirs, and the third block calculates the atmospheric temperature and lower ocean temperature at period t.

In addition, there is a generic block of equations expressing the upper bounding of the five climate quantities discussed in subsection 3.4.6. This generic equation is generated as many times as an upper bound on any climate variable is specified by the user, and is not generated if no upper bound is specified.

We now give the formulations of these constraints.

**Reminder:** the Climate Module formulation is activated at run time from the data handling system, which in turn set the $SET CLI YES switch.

General notation:
- \( D(t) \): duration of period \( t \), \( t=1 \) to \( T \)
- \( B(t) \): first year in period \( t \), \( t=1 \) to \( T \)
- \( m(t) \): milestone year of period \( t \) (approximate middle year of period, defined as \( m(t) = B(t) + \left\lfloor \frac{(D(t) - 1)/2} \right\rfloor \))
- \( y \): designates a year, while \( t \) designates a period (ranging from 1 to \( T \))
- \( Y \): designates the calibration year, which can be chosen by the user to be either \( B(1)-1 \), \( m(1)-1 \), or \( m(1) \), see section 3.2 above.

Table A-5. Climate Module specific constraints (all in the GAMS file equ_ext.cli).

<table>
<thead>
<tr>
<th>Constraints (Indexes)</th>
<th>Constraint Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EQ_CLITOT (cm_var,t)</td>
<td>Defines the amount of global greenhouse gas emissions in each period; defines the amount of total radiative forcing from the greenhouse gas concentrations in each period ( t ).</td>
</tr>
<tr>
<td>EQ_CLICONC (cm_var, cm_box,t)</td>
<td>Defines the mass of each greenhouse gas ( cm_var ) in each reservoir ( cm_box ) at the end of the milestone ( m(t) ) of period ( t ).</td>
</tr>
<tr>

<td>Defines the temperature increase in the each reservoir ( cm_box ) (the lower atmosphere and the lower ocean layer) over its pre-industrial temperature measured at the end of milestone ( m(t) ) of period ( t ).</td>
</tr>
<tr>
<td>EQ_CLIMAX (y,cm_var)</td>
<td>Imposes an upper bound on any or all of the climate variables ( cm_var ) (CO₂-GTC, CH₄-MT, N₂O-MT, CO₂-ATM, CO₂-PPM, CH₄-PPB, N₂O-PPB, FORCING, DELTA-ATM), at any desired year ( y ), according to the user-defined input parameter CM_MAXC.</td>
</tr>
</tbody>
</table>
5.1 EQ_CLITOT(cm_var,t)

**Description:** Defines the total amount of aggregate climate indicator in period t.

**Purpose:** This constraint defines the amount of global greenhouse gas emissions in each period and the amount of total radiative forcing from the greenhouse gas concentrations in each period t. This equation is generated in each time period for all indicators considered.

**Units:** Global emission units (GtC, Mt) or forcing units (W/m2)

**Type:** Binding. The equation is an equality (=) constraint.

**Interpretation of the results:**
- **Primal:** The level of this constraint must be zero in a feasible solution.
- **Dual variable:** The dual variables represent the marginal prices of the global emissions / forcing (when undiscounted).

**Remarks:**
- For CO2, the linear forcing function parameters $CM\_LINFOR_{t,cm\_emis,'FX'}$ and $CM\_LINFOR_{t,cm\_emis,'N'}$ are automatically calculated by the model generator from any user-defined $CM\_LINFOR_{t,cm\_emis,'LO'}$ and $CM\_LINFOR_{t,cm\_emis,'UP'}$.

**Equation:**

$$EQ\_CLITOT_{cm\_tkind,t} \forall \left( t \in \text{milestonyr} \right)$$

$$\sum_{cm\_tkind@cm\_emis} \sum_{(r,c,s)@rtcs\_varc_{t,s}} \sum_{cm\_emis} \left( CM\_LINFOR_{r,c,cm\_tkind,cm\_emis,'N'} \times \right)$$

$$+ \sum_{cm\_emis,cm\_tkind} \left( \sum_{cm\_atbox_{cm\_emis,cm\_box}} \sum_{cm\_boxmap_{cm\_emis,cm\_var,cm\_box}} CM\_LINFOR_{r,c,cm\_tkind,cm\_emis,'FX'} \right)$$

$$+ CM\_EXOFORC_{t} \{=\} \sum_{cm\_tkind,t} VAR\_CLITOT_{cm\_tkind,t}$$
5.2 EQ_CLICONC(cm_var,cm_box,t)

Description: Defines the reservoir-specific amounts of concentration indicator in each period.

Purpose: Defines the dynamic relationship between emissions and the concentration in the reservoirs modelled for each greenhouse gas, such that the amount of concentration in reservoir $i$ and period $t$ may depend on the amounts of concentrations in any reservoir $k$ in period $t-1$, and on the emissions in period $t$.

Units: Global emission units (GtC, Mt).

Type: Binding. The equation is an equality (=) constraint.

Interpretation of the results:
Primal: The level of this constraint must be zero in a feasible solution.
Dual variable: The dual variable of this constraint in the solution is of little interest.

Remarks:
- See expressions for the transfer matrices on next page.
- The equations beyond the last milestone year $m(T)$ are similar, but omitted here.

Equation:

\[
EQ_{-\text{CLICONC}}_{cm\_emis,cm\_box,t} \forall \left( t \in \text{milestonyr} \right)
\]

\[
\sum_{\text{cm\_boxmap}_{m\_emis,cm\_var,cm\_box2}} \text{VAR\_CLIBOX}_{cm\_var,t-1} \times \text{CM\_AA}_{cm\_emis,t,cm\_box,cm\_box2} + \\
\text{CM\_BB}_{cm\_emis,t,cm\_box} \times \text{VAR\_CLITOT}_{cm\_emis,t} + \\
\text{CM\_CC}_{cm\_emis,t,cm\_box} \times \text{VAR\_CLITOT}_{cm\_emis,t-1} + \\
\sum_{\text{miyr}_1} \text{CM\_CONST}_{cm\_var} \times \text{CM\_AA}_{cm\_emis,t,cm\_box,cm\_box2}
\]

\[
\{=\}
\sum_{\text{cm\_boxmap}_{m\_emis,cm\_var,cm\_box}} \text{VAR\_CLIBOX}_{cm\_var,t}
\]
\[ CM\_AA_{cm\_emis,t,i,j} = \{A_{ij}(t)\} = PHI^{n(t)} \quad (PHI^0 = I), \text{ where} \]

\[ \begin{bmatrix}
(1-PHI\_AT\_UP) & PHI\_UP\_AT & 0 \\
PHI\_AT\_UP & (1-PHI\_UP\_AT-PHI\_UP\_LO) & PHI\_LO\_UP \\
0 & PHI\_UP\_LO & (1-PHI\_LO\_UP)
\end{bmatrix} \]

\[ CM\_BB_{cm\_emis,t,i} = \{BB_{it}(t)\} \text{ is the first column of the matrix:} \]

\[ BB(t) = \sum_{i=0}^{p(t)-1} PHI^i \quad \text{ if } p(t) \geq 1 \]

\[ BB(t) = 0 \quad \text{ if } p(t) = 0 \]

\[ CM\_CC_{cm\_emis,t,i} = \{CC_{i1}(t)\} \text{ is the first column of the matrix:} \]

\[ CC(t) = \sum_{i=p(t)}^{n(t)-1} PHI^i \quad \text{ if } n(t) \geq p(t) + 1 \]

\[ CC(t) = 0 \quad \text{ if } n(t) = p(t) \]

\[ p(t) = \left\lfloor \frac{D(t)+1}{2} \right\rfloor, \quad n(t) = m(t) - m(t-1) \quad \text{ if } t \neq 1, \]

\[ p(t) = m(t) - Y, \quad n(t) = p(t) \quad \text{ if } t = 1 \]

\[ D(t) \text{ is the number of years in period } t, \text{ and } m(t) \text{ is the middle year of period } t \text{ defined as} \]

\[ m(t) = B(t) + \left\lfloor \frac{D(t)-1}{2} \right\rfloor \]

\[ \lfloor x \rfloor \text{ denotes the largest integer smaller than or equal to } x \]
5.3 EQ_CLITEMP(cm_var,cm_box,t)

Description: Defines the reservoir-specific amounts of temperature indicator in each period.

Purpose: Defines the dynamic relationship between forcing and the temperature increase in the reservoirs modelled, such that the amount of temperatures increase in reservoir i and period t may depend on the amounts of temperature increase in any reservoir k in period t–1, and on the radiative forcing in period t.

Units: Global temperature units (°C).

Type: Binding. The equation is an equality (=) constraint.

Interpretation of the results:
Primal: The level of this constraint must be zero in a feasible solution.
Dual variable: The dual variable of this constraint in the solution is of little interest.

Remarks:
- See expressions for the transfer matrices on next page.
- The equations for years beyond m(T) are similar, but omitted here.

Equation:

\[ EQ \_\_CLITEMP_{cm\_box,t} \forall \{t \in \text{milestoneyr}\} \]

\[
\sum_{\text{cm\_boxmap}\_\text{FORCING} \_\text{cm\_varem\_box2}} \\text{VAR\_CLIBOX}_{cm\_var,t-1} \times \text{CM\_AA}_{FORCEING',t,cm\_boxcm\_box2} + \]

\[
\text{CM\_BB}_{FORCEING',t,cm\_box} \times \text{VAR\_CLITOT}_{FORCEING',t} + \]

\[
\text{CM\_CC}_{FORCEING',t,cm\_box} \times \text{VAR\_CLITOT}_{FORCEING',t-1} + \]

\[
\sum_{\text{cm\_boxmap}\_\text{FORCING} \_\text{cm\_varem\_box2}} \text{CM\_CONST}_{cm\_var} \times \text{CM\_AA}_{FORCEING',t,cm\_boxcm\_box2} \]

\{=\}

\[
\sum_{\text{cm\_boxmap}\_\text{FORCING} \_\text{cm\_varem\_box}} \text{VAR\_CLIBOX}_{cm\_var,t} \]
\[ CM_{AA_{FORCING:t,i,j}} = \{ A_{ij}(t) \} = PHI^n(t) \quad (PHI^0 = I) \]

\( PHI \) is the 3 \times 3 matrix:

\[
\begin{bmatrix}
(1 - SIGMA1 \times (LAMBDA + SIGMA2)) & SIGMA1 \times SIGMA2 & 0 \\
SIGMA3 & (1 - SIGMA3) & 0 \\
0 & 0 & 0
\end{bmatrix}
\]

\[ CM_{BB_{FORCING:t,i,i}} = \{ BB_{ii}(t) \} \] is the first column of the matrix:

\[ BB(t) = SIGMA1 \times \sum_{i=0}^{n(t)-1} \frac{n(t)-i}{n(t)} \times PHI^i \]

\[ CM_{CC_{FORCING:t,i,j}} = \{ CC_{ij}(t) \} \] is the first column of the matrix:

\[ CC(t) = SIGMA1 \times \sum_{i=0}^{n(t)-1} \frac{i}{n(t)} \times PHI^i \]

\( n(t) = m(t) - m(t-1) \quad if \ t \neq 1, \)

\( n(t) = m(t) - Y \quad if \ t = 1 \)

\( D(t) \) is the number of years in period \( t \), and \( m(t) \) is the middle year of period \( t \) defined as:

\[ m(t) = B(t) + \left\lfloor \frac{D(t) - 1}{2} \right\rfloor \]

\( \lfloor x \rfloor \) denotes the largest integer smaller than or equal to \( x \)
5.4 EQ_CLIMAX(y,cm_var)

Description: Constraint that sets an upper bound on the climate indicator in a given year.

Purpose: To set an upper bound for a climate indicator variable in any desired year y. The variables that can be bounded are the total global emissions and the total radiative forcing (VAR_CLITOT), the atmospheric concentrations of greenhouse gases (sum of VAR_CLIBOX variables), and the increase in atmospheric temperature (VAR_CLIBOX). The bounds can be specified by using the CM_MAXC_y,cm_var attribute.

Units: Units of the variable(s) bounded.

Type: Binding. The equation is a less than or equal to inequality (≤) constraint.

Interpretation of the results:
Primal: The level of this constraint must be less than or equal to zero in a feasible solution.

Dual variable: The dual variable of this constraint in the solution may be used to derive the marginal price of the climate indicator constrained (when undiscounted; global dual values are, ex officio, reported without undiscounting, as no well-defined “global discount factors” exist, only regional ones).

Remarks:
- The CM_MAXC bounds defined on CO2-ATM are automatically converted into equivalent bounds on CO2-PPM.
- The coefficients α_y and β_y in the equations are such that y = α_y (m(t)−y) + β_y (y−m(t−1)), for all y in the range m(t−1) < y ≤ m(t).

Equation:

\[ EQ_{\_CLIMAX} y,cm\_var \quad \forall \left[ \left( y, cm\_var \right) \mid CM\_MAXC_{y,cm\_var} \right] \]

Case A. For total emissions, up to m(T)

\[ \alpha_y \times VAR\_CLITOT_{cm\_emis,t} + \beta_y \times VAR\_CLITOT_{cm\_emis,t} \leq CM\_MAXC_{y,cm\_emis} \]
Case B. For atmospheric GHG concentrations, up to m(T):

\[ \sum \alpha_y \times VAR_{\_CLIBOX_{\_cm\_var\_t-1}} + \beta_y \times VAR_{\_CLIBOX_{\_cm\_var\_t}} \leq CM_{\_MAXC_{\_y,\_cm\_var}} \]

Case C. For total radiative forcing, up to m(T):

\[ \alpha_y \times VAR_{\_CLITOT_{\_FORCING\_t-1}} + \beta_y \times VAR_{\_CLITOT_{\_FORCING\_t}} \leq CM_{\_MAXC_{\_y,\_FORCING\_t}} \]

Case D. For increase in global atmospheric temperature, up to m(T):

\[ \sum \alpha_y \times VAR_{\_CLIBOX_{\_cm\_var\_t-1}} + \beta_y \times VAR_{\_CLIBOX_{\_cm\_var\_t}} \leq CM_{\_MAXC_{\_y,\_cm\_var}} \]

Case E. For atmospheric GHG concentrations, beyond m(T):

\[ \sum VAR_{\_CLIBOX_{\_cm\_var\_y}} \leq CM_{\_MAXC_{\_y,\_cm\_var}} \]

Case F. For total radiative forcing, beyond m(T):

\[ VAR_{\_CLITOT\_FORCING\_y} \leq CM_{\_MAXC_{\_y,\_FORCING\_y}} \]

Case G. For increase in global atmospheric temperature, beyond m(T):

\[ \sum VAR_{\_CLIBOX_{\_cm\_var\_y}} \leq CM_{\_MAXC_{\_y,\_cm\_var}} \]

Appendix B  Damage Cost Functions

1  Introduction

This Appendix contains the documentation on the Damage Cost Function extensions for the TIMES model. The chapter contains 6 sections: section 2 contains the mathematical formulation, section 3 describes the parameters for the Damage Cost Functions, and section 4 gives two examples. Finally, section 5 describes the variables and section 6 describes the equations.

The Damage Cost Function option of TIMES is intended for modelers who wish to evaluate the environmental externalities caused by an energy system. For instance, emissions of toxic or environmentally harmful pollutants from the energy system create social costs linked to impacts of the pollution on human health and the environment. In another example, in global studies of GHG emissions, it may be of interest to evaluate the impact of GHG emissions on concentrations and ultimately on damages created by climate change induced by increased concentration of GHGs.

Until recently, in most studies involving bottom-up models, emission externalities have been modeled in one of two ways: either by introducing an emission tax, or by imposing emission caps. In the first case, the tax is (ideally) supposed to represent the external cost created by one unit of emission. However, using a tax assumes that the cost is a linear function of emissions. In the second approach, it is assumed that such a cost is unknown but that exogenous studies (or regulations, treaties, etc.) have defined a level of acceptable emissions that should not be exceeded. However, using this approach is akin to making the implicit assumption that emissions in excess of the cap have an infinite external cost. Both of these approaches have merit and have been successfully applied to many energy system model studies.

It is however possible to extend these two approaches by introducing an option to better model the cost of damages created by emissions. The damage function option discussed in this document extends the concept of an emission tax by modeling more accurately the assumed cost of damages due to emissions of a pollutant.
2 Mathematical formulation

We now describe the mathematical formulation used for the damage cost functions. With respect to optimization, two distinct approaches to account for damage costs can be distinguished:

1. Environmental damages are computed ex-post, without feedback into the optimization process, and
2. Environmental damages are part of the objective function and therefore taken into account in the optimization process.

In both approaches, a number of assumptions are made:

- Emissions in each region may be assumed to cause damage only in the same region or, due to trans-boundary pollution, also in other regions; however, all damage costs are allocated to the polluters in the source region, in accordance with the Polluter Pays Principle, or Extended Polluter Responsibility;
- Damages in a given time period are linked to emissions in that same period only (damages are not delayed, nor are they cumulative); and
- Damages due to several pollutants are the sum of damages due to each pollutant (no cross impacts).

In a given time period, and for a given pollutant, the damage cost is modeled as follows:

\[ DAM(EM) = \alpha \cdot EM^{\beta+1} \]  

where:
- \( EM \) is the emission in the current period;
- \( DAM \) is the damage cost in the current period;
- \( \beta \geq 0 \) is the elasticity of marginal damage cost to amount of emissions; and
- \( \alpha > 0 \) is a calibrating parameter, which may be obtained from dose-response studies that allow the computation of the marginal damage cost per unit of emission at some reference level of emissions.

If we denote the marginal cost at the reference level \( MC_0 \), the following holds:

\[ MC_0 = \alpha \cdot (\beta + 1) \cdot EM_0^{\beta} \]  

where \( EM_0 \) is the reference amount of emissions. Therefore expression (1) may be re-written as:

\[ DAM(EM) = MC_0 \cdot \frac{EM^{\beta+1}}{(\beta + 1) \cdot EM_0^\beta} \]  

(3)
The marginal damage cost is therefore given by the following expression:

$$MC(EM) = MC_0 \cdot \frac{EM^\beta}{EM_0^\beta}$$

(4)

The approach to damage costs described in this section applies more particularly to local pollutants. Extension to global emissions such GHG emissions requires the use of a global TIMES model and a reinterpretation of the equations discussed above.

The modeling of damage costs via equation (3) introduces a non-linear term in the objective function if the $\beta$ parameter is strictly larger than zero. This in turn requires that the model be solved via a Non-Linear Programming (NLP) algorithm rather than a LP algorithm. However, the resulting Non-Linear Program remains convex as long as the elasticity parameter is equal to or larger than zero. For additional details on convex programming, see Nemhauser et al (1989). If linearity is desired (for instance if problem instances are very large), we can approximate expression (3) by a sequence of linear segments with increasing slopes, and thus obtain a Linear Program.

The linearization can be done by choosing a suitable range of emissions, and dividing that range into $m$ intervals below the reference level, and $n$ intervals above the reference level. We also assume a middle interval centered at the reference emission level. To each interval corresponds one step variable $S$. Thus, we have for emissions:

$$EM = \sum_{i=1}^{m} S_{i}^{lo} + S_{i}^{mid} + \sum_{i=1}^{n} S_{i}^{up}$$

(5)

The damage cost can then be written as follows:

$$DAM(EM) = \sum_{i=1}^{m} MC_{i}^{lo} \cdot S_{i}^{lo} + MC_0 \cdot S_{i}^{mid} + \sum_{i=1}^{n} MC_{i}^{up} \cdot S_{i}^{up}$$

(6)

where:

- $MC_{i}^{lo}$ and $MC_{i}^{up}$ are the approximate marginal costs at each step below and above the reference level as shown in (7) below; and
- $S_{i}^{lo}$, $S_{i}^{mid}$ and $S_{i}^{up}$ are the non-negative step variables for emissions. Apart from the final step, each step variable has an upper bound equal to the width of the interval. In this formulation we choose intervals of uniform width on each side of the reference level. However, the intervals below and above the reference level can have different sizes. The width of the middle interval is always the average of the widths below and above the reference level.

The approximate marginal costs at each step can be assumed to be the marginal costs at the center of each step. If all the steps intervals are of equal size, the marginal costs for the steps below the reference level are obtained by the following formula:
\[ MC_{i}^{lo} = MC_{0} \cdot \left( \frac{(i - 0.5)}{(m + 0.5)} \right)^{\beta} \]  

(7)

Formulas for the marginal costs of the other steps can be derived similarly.

The TIMES implementation basically follows the equations shown above. Both the non-linear and linearized approaches can be used. However, in order to provide some additional flexibility, the implementation supports also defining a threshold level of emissions, below which the damage costs are zero. This refinement can be taken into account in the balance equation (5) by adding one additional step variable having an upper bound equal to the threshold level, and by adjusting the widths of the other steps accordingly. The threshold level can also easily be taken into account in the formulas for the approximate marginal costs.

In addition, the implementation supports different elasticities and step sizes to be used below and above the reference level. See Section 3 for more details.
3 Switches and Parameters

3.1 Activating the Damage Cost Functions

Like all other aspects of TIMES, the user describes the Damage Cost Functions by means of a Set and the Parameters and Switches described in this chapter.

As discussed in Section 2, the TIMES Damage Cost Function facility permits the assessment of environmental externalities by means of two approaches to determine the impact or cost of damages arising from emissions: ex-post calculation and internalized damage costs. The second approach can be further divided into the non-linear and linear formulations, and therefore the following three approaches are available in Standard TIMES:

1. The environmental damages are computed ex-post, without feedback into the optimization process;
2. The environmental damages are a linearized part of the objective function and therefore taken into account in the optimization process;
3. The environmental damages are a non-linear part of the objective function and therefore taken into account in the optimization process.

The user can control whether or not the damage costs are activated in the objective function by means of the switch $SET DAMAGE LP/NLP/NO. This switch is provided by the data handling system according to how the user wishes the option to be included:

- $SET DAMAGE LP
- $SET DAMAGE NLP
- $SET DAMAGE NO

The setting $SET DAMAGE LP is the default, and activates the linearized formulation of damage costs, with the costs included in the objective function. The setting $SET DAMAGE NLP activates the non-linear damage cost option, with the costs included in the objective function. The setting $SET DAMAGE NO causes the damage costs only to be computed ex-post, without feedback into the optimization process.

Note that owing to the non-linear nature of the modified objective function that endogenizes the damages, the NLP damage option requires non-linear solution methods that can lead to much larger resource utilization compared to LP models. In addition, the options with an augmented objective function cannot be currently activated with the non-linear TIMES-MACRO model variant. However, the linear option LP can be used together with the decomposed MACRO_MSA option.
3.2 Input parameters

All the parameters for describing damage functions are available in the VEDA-FE shell, where they may be specified. All parameters have a prefix 'DAM_' in the GAMS code of the model generator. The parameters are discussed in more detail below:

1. The parameter **DAM_COST** is used to specify the marginal damage cost at the reference level of emissions. The parameter has a year index, which can be utilized also for turning damage accounting on/off for an emission in a period (by specifying an EPS value for the cost). **DAM_COST** is interpolated/extrapolated by default, but unlike other cost parameters, the interpolation is sparse, and the costs are assumed to be constant within each period.

2. The parameter **DAM_BQTY** is used to specify the reference level of emissions. If not specified or set to zero, the marginal damage costs will be assumed constant, and no emission steps are used.

3. The parameter **DAM_ELAST** is used to specify the elasticity of marginal damage costs to emissions in the lower and upper direction. If specified in one direction only, the elasticity is assumed in both directions. If neither is specified, the marginal damage costs will be constant in both directions.

4. The parameter **DAM_STEP** can be used for specifying the number of emission steps below and above the reference level of emissions. The last step above the reference level will always have an infinite bound. If the number of steps is not provided in either direction, but the elasticity is, one step is assumed in that direction. If a non-zero **DAM_STEP**(r,c,'N') is specified, the damage costs for commodity c in region r are not included in the objective. If the NLP formulation is used (DAMAGE=NLP), all **DAM_STEP** parameters will be ignored.

5. The parameter **DAM_VOC** can be used for specifying the variation in emissions covered by the emission steps, both in the lower and upper direction. The variation in the lower direction should be less than or equal to the reference level of emissions. If the lower variation is smaller than **DAM_BQTY**, the damage costs.

The input parameters are listed in Table B-1.
Table B-1. Input parameters for the TIMES Damage Cost Functions.

\(^{47}\) The first row contains the parameter name, the second row contains in brackets the index domain over which the parameter is defined.

\(^{48}\) This column gives references to related input parameters or sets being used in the context of this parameter as well as internal parameters/sets or result parameters being derived from the input parameter.

\(^{49}\) This column lists the unit of the parameter, the possible range of its numeric value [in square brackets] and the inter-/extrapolation rules that apply.

\(^{50}\) An indication of circumstances for which the parameter is to be provided or omitted.

\(^{51}\) Equations or variables that are directly affected by the parameter.

\(^{52}\) Abbreviation i/e = inter-/extrapolation
3.3 Reporting parameters

There is only one reporting parameter specifically related to the Damage Cost functions. The parameter represents the undiscounted damage costs by region, period and emission commodity. The parameter has two flavours; the first one is for standard TIMES and the second one for stochastic TIMES:

- CST_DAM(r,t,c): Annual damage costs from emission c in region r.
- SCST_DAM(w,r,t,c): Annual damage costs from emission c in region r and stochastic scenario w.

However, in addition the standard reporting parameters REG_WOBJ, and REG_ACOST are augmented with damage costs results, using the label 'DAM'/DAM-EXT' to distinguish damage costs from other cost components.

These parameters are included in the .vdd files that describe the parameters to be transferred to VEDA-BE under standard TIMES and stochastic TIMES. Therefore, the corresponding result parameter is always available in VEDA-BE whenever Damage Cost functions have been defined, even with the setting DAMAGE=NO.

The damage costs are always reported by using the accurate non-linear expressions, even if the linearized formulation is chosen for the augmented objective function.

Table B-2. Reporting parameters for the TIMES Damage cost functions.

</tbody>
</table>
4 Examples

Assume that we wish to define linearized damage costs for the emission commodity 'EM' so that the cost function has the following properties:

- The reference level of emissions is 80 units;
- The marginal cost at the reference level are 10 cost units per emission unit;
- The cost elasticity is 1 in the lower direction, and 0.7 in the upper direction;

The damage function can be specified with the following parameters:

```plaintext
PARAMETER DAM_COST / REG.2000.EM.CUR 10 /;
PARAMETER DAM_BQTY / REG.EM 80 /;
PARAMETER DAM_ELAST / REG.EM.LO 1, REG.EM.UP 0.7 /;
```

As we did not specify the number of steps, but we did specify the elasticities in both directions, the number of steps is assumed to be 1 in both directions. The resulting damage cost function is illustrated in Figure 15. Because the damage function has a very coarse representation, the total costs have notable deviations from the accurate non-linear function. Note that the step size has been automatically determined to be \( \text{DAM_BQTY}/(\text{DAM_STEP}+0.5) = 80/1.5 \). However, the last step has no upper bound.

Assume next that we would like to refine the damage function by the following specifications:

![Figure 15. Example of a linearized damage function with 1+1+1 steps (1 lower step, 1 middle step, 1 upper step).](image)
- We want to have 5 steps below the reference, and 3 steps above it;
- The threshold level of damage costs is 20 units of emissions;
- The steps above the reference level should cover 100 units of emissions.

The damage function can be specified with the following parameters:

```
PARAMETER DAM_COST / REG.2000.EM.CUR 10 /;
PARAMETER DAM_BQTY / REG.EM 80 /;
PARAMETER DAM_ELAST / REG.EM.LO 1, REG.EM.UP 0.7 /;
PARAMETER DAM_STEP / REG.EM.LO 5, REG.EM.UP 3 /;
PARAMETER DAM_VOC / REG.EM.LO 60, REG.EM.UP 100 /;
```

The resulting damage cost function is illustrated in Figure 16. The cost function follows now very closely the accurate non-linear function. Note that the step sizes derived from the VOC specifications are 10 units for the lower steps, 20 for the middle step, and 30 units for the upper steps. However, the last step of course has no upper bound.

![Figure B-16. Example of a linearized damage function with 1+5+1+3 steps (one zero cost step, 5 lower steps, one middle step, 3 upper steps).](image-url)
5 Variables

There are only two sets of new variables in the damage cost formulation, VAR_DAM and VAR_OBJDAM, which are shown below in Table B-3. The variables VAR_DAM represent the steps in the emissions in each period. In the linearized formulation, there are DAM_STEP(...,'LO') number of step variables on the lower side and DAM_STEP(...'UP') number of step variables on the higher side of emissions. In addition, one step variable of type 'FX' corresponds to the middle step that includes the reference level of emissions, and an optional additional step variable of type 'FX' corresponds to the zero-damage fraction of emissions, as defined by the difference between DAM_BQTY(,) and DAM_VOC(....'LO').

The variables VAR_OBJDAM represent the total discounted damage costs by region. The undiscounted costs in each period described in Section 2 are discounted and summed over all periods and emissions in each region. As emissions are in TIMES assumed to be constant within each period, damage costs are likewise assumed to be constant within each period.

Table B-3. Model variables specific to the Damage Cost Functions.

<table>

<td>The variable is equal to the sum of the total discounted damage costs in each region r with currency cur.</td>
</tr>
</tbody>
</table>
5.1 VAR_DAMAGE(r,t,c,bd,j)

Description: The amount of emission indicator c at cost step j in direction bd, in period t.

Purpose: This variable tracks the amount of an emission indicator by cost step and period, in both the lower and upper direction from the reference level.

Occurrence: The variable is generated for emission indicator that has damage costs specified, whenever the damage cost functions are included in the objective function.

Units: Units of the emission commodity c.

Bounds: This variable cannot be directly bounded by the user.

5.2 VAR_OBJ(r,'OBJDAM',cur)

Description: The total present value of damage costs by region.

Purpose: This variable is included in the objective function in order to include damage costs in the objective when requested by the user.

Occurrence: This variable is generated for each region when damage cost functions are included in the objective function.

Units: Currency units used for damage functions.

Bounds: This variable cannot be directly bounded by the user.
6 Equations

There are two blocks of equations generated for damage cost functions, whenever they are included in the objective function. The two equations related to the damage functions are listed and briefly described below in Table B-4. The equations include the balance of stepped emissions, the objective component for damage costs, and the augmented total objective function.

In addition, the standard TIMES objective function, EQ_OBJ, is augmented by the present value of the damage costs, as defined by the equation EQ_OBJDAM.

We now give the formulations of these constraints.

Reminder: the Damage Cost Functions are activated at run time from the data handling system, which in turn sets the switch $SET DAMAGE LP/NLP/NO.

Table B-4. Constraints specific to damage costs (in the GAMS file eqdamage.mod).

<table>
<thead>
<tr>
<th>Constraints (Indexes)</th>
<th>Constraint Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EQ_DAMAGE (r,t,c)</td>
<td>The balance equation between the stepped emission variables and the total emissions in each period.</td>
</tr>
<tr>
<td>EQ_OBJDAM (r,cur)</td>
<td>The total discounted damage costs by region, which will be added as a component to the objective function.</td>
</tr>
</tbody>
</table>
6.1 **EQ DAMAGE(r,t,c)**

**Description:** Allocates the total amount of emission indicator in period \( t \) to cost steps.

**Purpose:** This constraint allocates the total amount of emission indicator \( c \) to the cost steps of the linearized / non-linear damage cost functions in each period \( t \).

This equation is generated in each time period for all emission indicators considered.

**Units:** Units of the emission commodity \( c \).

**Type:** *Binding.* The equation is an equality (=) constraint.

**Remarks:**
- The damage costs can be defined either on the net production (VAR_COMNET) or the gross production (VAR_COMPRD) of the commodity \( c \). By default the damage costs are applied to the NET amount, unless \( DAM \_ELAST_{r,c,N} \) is also specified. \( DAM \_ELAST_{r,c,N} \) defines a multiplier for the Base prices to be added to the damage cost function, when it is to be applied to the gross production.
- The internal parameter \( DAM \_COEF_{r,t,c} \) is set to the base prices, if \( DAM \_ELAST_{r,c,N} \) is specified, and otherwise to 1.

**Equation:**

\[
EQ \_DAMAGE_{r,t,c} \equiv \big( rtc_{r,t,c} \land \exists(cur) : DAM \_COST_{r,t,c,cur} \big)
\]

\[
\sum_{(jj,bd) \in dam\_num_{r,c,bd}} \sum_{1 \leq jj} \sum_{var\_dam_{r,t,c,bd,j}} \left( DAM \_COEF_{r,t,c,t} \times \begin{cases} 
VAR \_COMNET_{r,t,c,ts} & \text{if } DAM \_ELAST_{r,c,N} \text{ not given} \\
VAR \_COMPRD_{r,t,c,ts} & \text{otherwise}
\end{cases} \right)
\]
6.2  \textbf{EQ_OBJDAM(r,cur)}

\textbf{Description:} Computes the present value of all damage costs by region and currency.

\textbf{Purpose:} Defines the variable \texttt{VAR_OBJ(r,'OBJDAM',cur)}, which represents the total present value of all damage costs in region \texttt{r}, having currency \texttt{cur}. This variable is included in the TIMES objective function.

\textbf{Units:} Currency units.

\textbf{Type:} \textit{Binding}. The equation is an equality (=) constraint.

\textbf{Remarks:}
- The internal parameter \texttt{DAM\_SIZE_{r,c,bd}} represents the sizes of cost steps of the dlinearized damage cost function, for both directions (bd=LO/UP) and for the middle step (bd=FX), as described above in Section 2.

\textbf{Equation:}

\[ EQ\_OBJDAM_{r,cur} \ni (rdcur_{r,cur}) \]

\textbf{Case A: Linearized functions}

\[ \sum_{(t,c) \in \{rt,se\} \setminus \text{DAM\_Cost}_{r,t,>0}} \text{DAM\_COST}_{r,t,cur} \times OBJ\_PVT_{r,t,cur} \times \]

\[ \left( \frac{\text{VAR\_DAM}_{r,t,c,LO,j}}{\text{DAM\_BQTY}_{r,c}} \times \frac{\text{DAM\_BQTY}_{r,c}}{\text{DAM\_ELAST}_{r,c,LO}} \times \left( \text{DAM\_BQTY}_{r,c} - \text{DAM\_VOC}_{r,c,LO'} + \text{DAM\_ELAST}_{r,c,LO'} \right) \times (j - 0.5) \right) + \]

\[ \sum_{jj \in \text{dam\_num}_{x,g,LO}} \left( \frac{\text{VAR\_DAM}_{r,t,c,FX',1}}{\text{DAM\_BQTY}_{r,c}} \times \frac{\text{DAM\_BQTY}_{r,c}}{\text{DAM\_ELAST}_{r,c,UP}} \times \left( \text{DAM\_BQTY}_{r,c} + \frac{\text{DAM\_SIZE}_{r,c,FX'}}{2} + \text{DAM\_ELAST}_{r,c,UP} \right) \right) \]

\[ \{=\} \]

\[ \text{VAR\_OBJ}_{r,'OBJDAM\_cur} \]
Case B: Non-linear functions

\[
\sum_{(t,c) \in \text{UTC\{\text{DAM}_\text{COST}_j,>0\}}} \text{DAM}_\text{COST}_{r,t,c,\text{cur}} \times \text{OBJ}_\text{PVT}_{r,t,c,\text{cur}} \times \\

Appendix C
Endogenous Technological Learning (ETL)

1 Introduction

As discussed in Chapter 11 of Part I, there are situations in which the rate at which a technology’s unit investment cost changes over time is a function of cumulative investment in the technology. In these situations, technological learning is called endogenous.

Mixed Integer Programming (MIP) is employed in order to model Endogenous Technological Learning (ETL) in TIMES. As has already been noted in the case of Lumpy Investments, MIP problems are much more difficult to solve than standard LP problems, and so the ETL feature should be applied only where it is deemed necessary to model a limited number of technologies as candidates for Endogenous Technological Learning. This caution is especially required for large-scale TIMES instances. Another important caveat is that ETL is relevant when the modeling scope is broad e.g. when a large portion of (or perhaps the entire) world energy system is being modeled, since the technological learning phenomenon rests on global cumulative capacity of a technology, and not on the capacity implemented in a small portion of the world.

In this chapter we provide the data and modeling details associated with modeling Endogenous Technological Learning (ETL) in TIMES. The implementation of ETL in TIMES is based on the realization in the MARKAL model generator. The major part of the MARKAL code for ETL could be transferred to TIMES. Accordingly the description of ETL presented here follows the MARKAL documentation of ETL. To this end the next three sections will address the Sets, Parameters, Variables, and Equations related to the Endogenous Technological Learning option, including the special clustered learning ETL option where a component common to several technologies learns, thereby benefiting all the related (clustered) technologies.

2 Sets, Switches and Parameters

Like all other aspects of TIMES the user describes the ETL components of the energy system by means of a Set and the Parameters and Switches described in this chapter. Table C-1 and Table C-2 below describe the User Input Parameters, and the Matrix Coefficient and Internal Model Sets and Parameters, respectively, that are associated with the Endogenous Technological Learning option. Note that the special clustered learning ETL option requires one additional User Input Parameter (ETL-CLUSTER), and two additional Matrix Coefficient/Internal Model Parameters (CLUSTER and NTCHTEG).

Besides the basic data described in Table the user controls whether or not the ETL component is activated by means of the $SET ETL ‘YES’ switch. This switch is provided by the data handling system when the user indicates that the ETL option is to be included in a run. This permits the easy exclusion of the feature if the user does not want to perform a MIP solve without having to remove the ETL data.
Table C-1. Definition of ETL user input parameters

The interval lengths on the vertical axis are chosen in such a way that each interval is twice as wide as the preceding one.</td>
</tr>
</tbody>
</table>
3 Variables

The variables that are used to model the Endogenous Technological Learning option in TIMES are presented in Table below. As is the case with the modeling of lumpy investments, the primary role of the variables and equations used to model ETL is to control the standard TIMES investment variable (VAR_NCAP) and the associated dynamic cost of these investments, so ETL is rather self-contained. That is the VAR_NCAP variable links the ETL decisions to the rest of the model, and the VAR_IC investment cost variable determines the associated contribution to the regional investment costs (VAR_OBJINV). Note that the special clustered learning ETL option does not require any additional variables, as compared with the modeling of endogenous technology learning when there are no clusters.

Table C-3. ETL-specific model variables

<table>
<thead>
<tr>
<th>Variable (Indexes)</th>
<th>Variable Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VAR_CCAP (r,t,p)</td>
<td>The cumulative investment in capacity for an ETL technology. This variable represents the initial cumulative capacity (CCAP0) plus investments in new capacity made up to and including the current period. This variable differs from the total installed capacity for a technology (VAR_CAP) in that it includes all investments in new capacity made up to and including the current period, whereas the latter only includes investments that are still available (i.e. whose life has not expired yet).</td>
</tr>
<tr>
<td>VAR_CCOST (r,t,p)</td>
<td>The cumulative cost of investment in capacity for an ETL technology. The cumulative cost is interpolated from the piecewise linear approximation of the cumulative cost curve.</td>
</tr>
<tr>
<td>VAR_DELTA (r,t,p,k)</td>
<td>Binary variable (takes the value 0 or 1) used for an ETL technology to indicate in which interval of the piecewise linear approximation of the cumulative cost curve the cumulative investment in capacity (VAR_CCAP) lies. A value of 1 for this variable for exactly one interval k indicates that VAR_CCAP lies in the k^{th} interval.</td>
</tr>
<tr>
<td>VAR_IC (r,t,p)</td>
<td>The portion of the cumulative cost of investment in capacity for an ETL technology (VAR_CCOST) that is incurred in period t, and so subject to the same discounting that applies to other period t investment costs. This variable is calculated as the difference between the cumulative costs of investment in capacity for periods t and t-1, and enters the regional investment cost part of the objective function (EQ_OBJINV).</td>
</tr>
<tr>
<td>VAR_LAMBD (r,t,p,k)</td>
<td>Continuous variable used for an ETL technology to represent the portion of cumulative investment in capacity (VAR_CCAP) that lies in the k^{th} interval of the piecewise linear approximation of the cumulative cost curve. For a given ETL technology and given time period, ETL model constraints involving this variable and the associated binary variable VAR_DELTA ensure that VAR_LAMBD is positive for exactly one interval k.</td>
</tr>
</tbody>
</table>
3.1 VAR_CCAP(r,t,p)

**Description:** The cumulative investment in capacity for an ETL technology.

**Purpose and Occurrence:** This variable tracks the cumulative investment in capacity for an ETL technology which then determines, along with the progress ratio, how much the investment cost is to be adjusted for the learning gains.

This variable is generated for each ETL technology in all time periods beginning from the period that the technology is first available. It appears in the cumulative capacity definition constraint (EQ_CUINV) that defines it as the initial cumulative capacity (CCAP0) plus investments in new capacity (VAR_NCAP) made up to and including the current period. It also appears in the cumulative capacity interpolation constraint (EQ_CC). This constraint equates VAR_CCAP(r,t,p) to the sum over k of the variables VAR_LAMBD(r,t,p,k) used to represent the cumulative investment in capacity lying in the k\textsuperscript{th} interval of the piecewise linear approximation of the cumulative cost curve.

**Units:** PJ/a, Gw, or Bvkm/a, or any other unit defined by the analyst to represent technology capacity.

**Bounds:** This variable is not directly bounded. It may be indirectly bounded by specifying a bound (NCAP_BND) on the level of investment in new capacity (VAR_NCAP).

3.2 VAR_CCOST(r,t,p)

**Description:** The cumulative cost of investment in capacity for an ETL technology.

**Purpose and Occurrence:** This variable defines the interpolated cumulative cost of investment in capacity in terms of the continuous variables VAR_LAMBD and the binary variables VAR_DELTA, and the internal model parameters ALPH and BETA. ALPH and BETA represent the intercepts on the vertical axis and the slopes, respectively, of the line segments in the piecewise linear approximation of the cumulative cost curve.

This variable is generated for each ETL technology in all time periods beginning from the period that the technology is first available. It appears in the cumulative cost interpolation equation (EQ_COS) that defines it. It also appears in the equations EQ_IC1 and EQ_IC2 that define the
VAR_IC variables that represent the portions of the cumulative cost of investment in capacity that are incurred in period t.

**Units:** Million 2000 US$, or any other unit in which costs are tracked.

**Bounds:** None.

### 3.3 VAR_DELTA(r,t,p,k)

**Description:** Binary variable (takes the value 0 or 1) used for an ETL technology to indicate in which interval of the piecewise linear approximation of the cumulative cost curve the cumulative investment in capacity (VAR_CCAP) lies.

**Purpose and Occurrence:** To indicate which step on the learning curve a technology achieves. A value of 1 for this variable for interval k, and zero values for intervals \( \neq k \), imply that the cumulative investment in capacity (VAR_CCAP) lies in the \( k^{th} \) interval of the piecewise linear approximation of the cumulative cost curve.

This binary variable, along with the associated continuous variable VAR_LAMBD, are generated for each ETL technology in all time periods beginning from the period that the technology is first available, and for each interval in the piecewise linear approximation. It appears in the constraint EQ_DEL, whose purpose is to ensure that, for each ETL technology in each period, it has a value of 1 for exactly one interval k (with zero values for intervals \( \neq k \)); and in the cumulative cost interpolation constraint (MR_COS). It also appears in the pair of constraints EQ_LA1 and EQ_LA2, whose purpose is to ensure that VAR_LAMBD, if positive for interval k, is between the two break points on the horizontal axis for interval k in the piecewise linear approximation. (See below under “Purpose and Occurrence” for the variable VAR_LAMBD.)

Finally, this binary variable appears in two constraints EQ_EXPE1 and EQ_EXPE2, whose purpose is to reduce the domain of feasibility of the binary variables and thereby improve solution time for the Mixed Integer Program (MIP).

**Units:** None. This is a binary variable that takes the value 0 or 1.

**Bounds:** This binary variable is not directly bounded.
3.4 VAR_IC(r,t,p)

**Description:** The portion of the cumulative cost of investment in capacity for an ETL technology (VAR_CCOST) that is incurred in period t.

**Purpose and Occurrence:** This variable represents the portion of the cumulative cost of investment in capacity for an ETL technology that is incurred in period t, and so is subject to the same discounting in the investment cost part of the objective function (EQ_OBJINV) that applies to other period t investment costs.

This variable is calculated as the difference between the cumulative costs of investment in capacity for period t and t-1, and is generated for each ETL technology in all time periods beginning from the period that the technology is first available. Apart from its appearance in the objective function, this variable appears in the constraints EQ_IC1 and EQ_IC2 that define it in the first period that the technology is available, and in subsequent periods, respectively. It also appears in the salvage of investments constraint (EQ_OBJSALV), which calculates the amount to be credited back to the objective function for learning capacity remaining past the modeling horizon.

**Units:** Million 2000 US$, or any other unit in which costs are tracked.

**Bounds:** None.

3.5 VAR_LAMBD(r,t,p,k)

**Description:** Continuous variable used for an ETL technology to represent the portion of cumulative investment in capacity (VAR_CCAP) that lies in the kth interval of the piecewise linear approximation of the cumulative cost curve.

**Purpose and Occurrence:** A positive value for this variable for interval k, and zero values for intervals ≠ k, imply that the cumulative investment in capacity (VAR_CCAP) lies in the kth interval of the piecewise linear approximation of the cumulative cost curve. This continuous variable, along with the associated binary variable VAR_DELTA, are generated for each ETL technology in all time periods beginning from the period that the technology is first available (START), and for each interval in the piecewise linear approximation.

Since this variable represents the portion of the cumulative investment in capacity (VAR_CCAP) that lies in the kth interval of the piecewise linear approximation of the cumulative cost curve, the value of
EQ_LAMBD – if positive – is required to be between CCAPK(k-1,p) and CCAP(k,p), where the internal model parameters CCAPK are the break points on the horizontal axis in the piecewise linear approximation of the cumulative cost curve. A zero value for VAR_LAMBD is also allowed. These requirements on the value of VAR_LAMBD are imposed via the pair of constraints EQ_LA1 and EQ_LA2, in which the value for VAR_LAMBD is subject to lower and upper bounds of CCAPK(k-1,p) * VAR_DELTA and CCAP(k,p) * VAR_DELTA respectively, where VAR_DELTA = VAR_DELTA(r,t,p,k) is the binary variable associated with VAR_LAMBD = VAR_LAMBD(r,t,p,k).

This variable also appears in the cumulative capacity interpolation constraint (EQ_CC), and the cumulative cost interpolation constraint (EQ_COS).

Units: PJ/a, Gw, or Bvkm/a, or any other unit defined by the analyst to represent technology capacity.

Bounds: The pair of constraints EQ_LA1 and EQ_LA2 that are discussed above have the effect of either bounding VAR_LAMBD between CCAPK(k-1,p) and CCAP(k,p), or forcing VAR_LAMBD to be zero.
4 Equations

The equations that are used to model the Endogenous Technological Learning option in TIMES are presented in Table C-4 below. Since the primary role of the variables and equations used to model ETL is to control the standard TIMES investment variable (VAR_NCAP) and the associated dynamic cost of these investments, ETL is rather self-contained. That is the VAR_NCAP variable links the ETL decisions to the rest of the model, and the VAR_IC investment cost variable determines the associated contribution to the regional investment cost part objective function (EQ_OBJINV). Note that the special clustered learning ETL option involves one additional equation (EQ_CLU), as compared with the modeling of endogenous technology learning where there are no clusters. IN BOX BELOW, ADD ANSWER or CHANGE TO "system"

Reminder: the ETL formulation is activated at run time from the data handling system, which in turn sets the $SET ETL ‘YES’ switch.

</tr>
</tbody>
</table>
4.1 \text{EQ\_CC}(r,t,p)

\textbf{Description:} The Cumulative Capacity Interpolation constraint for an ETL technology.

\textbf{Purpose and Occurrence:} This constraint defines the cumulative investment in capacity for a technology in a period (VAR\_CCAP) as the sum over all intervals k of the \textit{continuous} variables VAR\_LAMBD\!(r,t,p,k) that represent cumulative investment in capacity as lying in the k$^{\text{th}}$ interval of the piecewise linear approximation of the cumulative cost curve. This constraint links the cumulative capacity investment variable (VAR\_CCAP) to the variables VAR\_LAMBD. In combination with other ETL constraints, it is fundamental to ensuring the validity of the piecewise linear approximation of the cumulative cost curve.

This equation is generated in each time period for which the ETL technology is available.

\textbf{Units:} Technology capacity units.

\textbf{Type:} \textit{Binding}. The equation is an equality (=) constraint.

\textbf{Interpretation of the results:}
\textit{Primal:} The level of this constraint must be zero in a feasible solution.

\textit{Dual variable:} The dual variables of mixed integer problems have limited usefulness, as discussed in Section 10.3 of PART I.

\textbf{Equation}

\[ \text{EQ\_CC}_{r,t,p} \forall [ (p \in \text{teg}) \land ((r,t,p) \in rtp)] \]

Cumulative investment in capacity in the current period.

\[ \text{VAR\_CCAP}_{r,t,p} \]

\( \{=\} \)

Sum over all intervals k (in the piecewise linear approximation of the cumulative cost curve) of the \textit{continuous} variables VAR\_LAMBD in the current period t.

\[ \sum_{k} \text{VAR\_LAMBD}_{r,t,p,k} \]
4.2 EQ_CLU(r,t,p)

**Description:** For a key learning ETL technology it defines investment in new capacity (VAR_NCAP) as the weighted sum of investments in new capacity of the attached clustered technologies. The weights used are the numeric values of the CLUSTER parameter.

**Purpose and Occurrence:** Defines the relationship between investment in new capacity for a key learning ETL technology and investment in new capacity for the associated clustered technologies. This equation is generated in each time period for which the ETL technology is available. It is a key learning technology, that is, it has associated clustered technologies.

**Units:** Money units, e.g., million 2000 US$, or any other unit in which costs are tracked.

**Type:** Binding. The equation is an equality (=) constraint.

**Interpretation of the results:**

*Primal:* The level of this constraint must be zero in a feasible solution.

*Dual variable:* The dual variable (DVR_CLU) of this constraint in the MIP solution is of little interest.

**Remarks:** Activation of the special clustered learning ETL option occurs automatically if data is included for the CLUSTER parameter.

**Equation**

\[ \text{EQ}_{-\text{CLU}}(r,t,p) \equiv \left[ (p \in \text{teg}) \land \left( \text{NTCHTEG}_{r,p} > 0 \right) \right] \land \left[ ((r,t,p) \in rtp) \right] \]

Investment in new capacity (for key learning technology \( p \in \text{teg} \)) in period \( t \).

\[ \text{VAR}_{-\text{NCAP}}(r,t,p) \equiv \left\{ \begin{array}{c} \text{= } \\ \text{The weighted sum of the investments in new capacity in period } t \text{ of the clustered technologies } p' \text{ attached to the key learning technology } p \in \text{teg}, \text{ and whose START period is less than or equal to } t. \text{ The weights used are the numeric values of the CLUSTER parameter.} \end{array} \right\} \]

\[ \sum_{p'} \left\{ \left( \text{CLUSTER}_{r,p,p'} > 0 \right) \land ((r,t,p') \in rtp) \right\} \text{VAR}_{-\text{NCAP}}(r,t,p') \]
4.3 EQ_COS(r,t,p)

**Description:** The Cumulative Cost Interpolation constraint for an ETL technology.

**Purpose and Occurrence**

This constraint defines the interpolated cumulative cost of investment in capacity for a technology in a period (VAR_CCOST) in terms of the binary variables VAR_DELTA and the continuous variables VAR_LAMBD, and the internal model parameters ALPH and BETA, where ALPH and BETA represent the intercepts on the vertical axis and the slopes, respectively, of the line segments in the piecewise linear approximation of the cumulative cost curve. For a more precise definition, see “Equation” below. In combination with other ETL constraints, it is fundamental to ensuring the validity of the piecewise linear approximation of the cumulative cost curve. This equation is generated in each time for which the ETL technology is available.

**Units:** Money units, e.g., million 2000 US$, or any other unit in which costs are tracked.

**Type:** *Binding*. The equation is an equality (=) constraint.

**Interpretation of the results:**

*Primal:* The level of this constraint must be zero in a feasible solution.

*Dual variable:* The dual variables of mixed integer problems have limited usefulness, as discussed in Section 10.3 of PART I.

**Equation**

\[
EQ \_ COS \_ r,t,p \ \forall \left[ \left( p \in teg \right) \land \left( (r, t, p) \in rtp \right) \right]
\]

Interpolated cumulative cost of investment in capacity in the current period.

\[
\begin{align*}
VAR \_ CCOST & \quad r,t,p \\
\{=\} & \\
\sum_k (ALPH_k, p \cdot VAR \_ DELTA_{r,t,p,k} + BETA_k, p \cdot VAR \_ LAMBD_{r,t,p,k})
\end{align*}
\]

Sum over all intervals k (in the piecewise linear approximation of the cumulative cost curve) of ALPH times the *binary* variable VAR_DELTA plus BETA times the *continuous* variable VAR_LAMBD, for the current period t, where ALPH and BETA represent the intercepts on the vertical axis and the slopes, respectively, of the k-th interval.
4.4 EQ_CUINV(r,t,p)

Description: The Cumulative Capacity Definition constraint for an ETL technology.

Purpose and Occurrence: This constraint defines the cumulative investment in capacity of a technology in a period (VAR_CCAP) as the initial cumulative capacity (CCAP0) plus the sum of investments in new capacity made up to and including this period. This equation is generated in each time period for which the ETL technology is available.

Units: Technology capacity units.

Type: Binding. The equation is an equality (=) constraint.

Interpretation of the results:
Primal: The level of this constraint must be zero in a feasible solution.
Dual variable: The dual variables of mixed integer problems have limited usefulness, as mentioned above.

Equation

\[
EQ_{-}CUINV_{r,t,p} \forall [(p \in teg) \land ((r,t,p) \in rtp)]
\]

Cumulative investment in capacity in the current period.

\[
VAR_{-}CCAP_{r,t,p}
\]

\[
\{=\}
\]

Cumulative investment in capacity at the start of the learning process.

\[
CCAP0_{r,p} +
\]

Sum of the investments made since the technology is first available.

\[
\sum_{u \in rtp_{a,p} \land u \in t} VAR_{-}NCAP_{r,dt,p}
\]
4.5 EQ_DEL(r,t,p)

**Description:** The constraint for an ETL technology that ensures that in each time period there is exactly one interval k for which the binary variable VAR_DELTA(r,t,p,k) has value 1 (with zero values for intervals ≠ k).

**Purpose and Occurrence:** To ensure that only one of the binary variable VAR_DELTA(r,t,p,k) has value 1 for each technology. This constraint, in combination with other ETL constraints, is fundamental to ensuring the validity of the piecewise linear approximation of the cumulative cost curve. This equation is generated in each time period for which the ETL technology is available.

**Units:** None.

**Type:** Binding. The equation is an equality (=) constraint.

**Interpretation of the results:**

*Primal:* The level of this constraint must be 1 in a feasible solution.

*Dual variable:* The dual variables of mixed integer problems have limited usefulness, as already mentioned.

**Equation**

\[ EQ\_DEL_{r,t,p} \land ([p \in \text{teg}) \land ((r,t,p) \in rtp)] \]

Sum over all intervals k (in the piecewise linear approximation of the cumulative cost curve) of the binary variables VAR_DELTA in the current period t.

\[ \sum_{k} VAR\_DELTA_{r,t,p,k} \]

\[ \{\neq\} 1 \]
4.6 **EQ_EXPE1(r,t,p,k)**

**Description:** One of two constraints for an ETL technology to improve MIP solution time by reducing the domain of feasibility of the binary variables VAR_DELTA.

**Purpose and Occurrence:** To improve MIP solution time this constraint takes advantage of the observation that cumulative investment is increasing with time, thus ensuring that if the cumulative investment in period \( t \) lies in segment \( k \), then it will not lie in segments \( k-1, k-2, \ldots, 1 \) in period \( t+1 \). This equation is generated for each ETL technology in each time period, for which the technology is available, and excluding the final period (TLAST), and for each interval \( k \) in the piecewise linear approximation of the cumulative cost curve.

**Units:** None.

**Type:** *Binding.* The equation is a greater than or equal to \((\geq)\) constraint.

**Interpretation of the results:**

*Primal:* The level of this constraint must be greater than or equal to zero in a feasible solution.

*Dual variable:* The dual variables of mixed integer problems have limited usefulness, as already mentioned.

**Equation**

\[
EQ\_EXPE1_{r,t,p,k} \forall [(p \in teg) \land ((r, t, p) \in rtp) \land (t < TLAST)]
\]

\[
\sum_{j \leq k} (VAR\_DELTA_{r,t,p,j}) \geq 0
\]

Sum over intervals \( j \leq k \) of binary variables VAR_DELTA(r,t,p,j), for the \( k^{th} \) interval, in period \( t \).

\[
\sum_{j \leq k} (VAR\_DELTA_{r,t+1,p,j}) \geq 0
\]

Sum over intervals \( j \leq k \) of binary variables VAR_DELTA(r,t+1,p,j), for the \( k^{th} \) interval, in period \( t+1 \).
4.7 \textbf{EQ\_EXPE2}(r,t,p,k)

\textbf{Description:} Second of two constraints for an ETL technology to improve MIP solution time by reducing the domain of feasibility of the binary variables VAR\_DELTA. Both constraints rely on the observation that cumulative investment is increasing as time goes on.

\textbf{Purpose and Occurrence:} To improve MIP solution times this constraint is derived from the observation that if cumulative investment in period \(t\) lies in segment \(k\), then it must lie in segment \(k\) or \(k+1\) or \(k+2\) etc … in period \(t+1\).

This equation is generated for each ETL technology in each time period, for which the technology is available, and excluding the final period (TLAST), and for each interval \(k\) in the piecewise linear approximation of the cumulative cost curve.

\textbf{Units:} None.

\textbf{Type:} \textit{Binding}. The equation is a less than or equal to (\(\leq\)) constraint.

\textbf{Interpretation of the results:}

\textit{Primal:} The level of this constraint must be less than or equal to zero in a feasible solution.

\textit{Dual variable:} The dual variables of mixed integer problems have limited usefulness, as already mentioned.

\textbf{Equation}

\[ \text{EQ\_EXPE2}_{r,t,p,k} \forall \left[ (p \in \text{teg}) \wedge ((r,t,p) \in rtp) \wedge (t < \text{TLAST}) \right] \]

\[ \sum_{j \geq k} (\text{VAR\_DELTA}_{r,t,p,j}) \]

\[ \{\leq\} \]

Sum over intervals \(j \geq k\) of binary variables VAR\_DELTA\((r,t,p,j)\), for the \(k^{th}\) interval, in period \(t\).

\[ \sum_{j \geq k} (\text{VAR\_DELTA}_{r,t+1,p,j}) \]

Sum over intervals \(j \geq k\) of binary variables VAR\_DELTA\((r,t,p,j)\), for the \(k^{th}\) interval, in period \(t+1\).
4.8 \textbf{EQ\_IC1(r,t,p)}

\textbf{Description:} The constraint for an ETL technology that defines the portion of the cumulative cost of investment in capacity (VAR\_IC) that is incurred in period t, where t = first period of model horizon.

\textbf{Purpose and Occurrence:} To determine the variable VAR\_IC which represents the current investment cost incurred in the first period a learning technology is available according to the cumulative investments made in that period. VAR\_IC then enters the regional investment cost part of the objective function (EQ\_OBJINV) subject to the same discounting that applies to other period t investment costs. This equation is generated for the first period of the model horizon.

\textbf{Units:} Money units, e.g., million 2000 US$, or any other unit in which costs are tracked.

\textbf{Type:} \textit{Binding}. The equation is an equality (=) constraint.

\textbf{Interpretation of the results:}
\textit{Primal:} The level of this constraint must be zero in a feasible solution.
\textit{Dual variable:} The dual variables of mixed integer problems have limited usefulness, as already mentioned.

\textbf{Equation}

\[ EQ\_IC1_{r,t,p} \forall (p \in teg) \land (t = MIYR\_V1) \]

The portion of the cumulative cost of investment in capacity that is incurred in period t, in this case the first period the technology is available.

\[ VAR\_IC_{r,t,p} \{=\} \]

The cumulative cost of investment in new capacity in the first period t (t = MIYR\_V1).

\[ VAR\_CCOST_{r,t,p} - \]

The initial cumulative cost of investment in new capacity for a learning technology.

\[ CCOST0 \]
4.9 EQ_IC2(r,t,p)

Description: The constraint for an ETL technology that defines the portion of the cumulative cost of investment in capacity that is incurred in each period t other than the first period.

Purpose and Occurrence: To determine the variable VAR_IC which represents the current investment cost incurred in period t according to the cumulative investments made thus far, where VAR_IC then enters the regional investment cost part of the objective function (EQ_OBJINV) subject to the same discounting that applies to other period t investment costs. This equation is generated in each time period other than the first period of the model horizon.

Units: Money units, e.g., million 2000 US$, or any other unit in which costs are tracked.

Type: Binding. The equation is an equality (=) constraint.

Interpretation of the results:
Primal: The level of this constraint must be zero in a feasible solution.
Dual variable: The dual variables of mixed integer problems have limited usefulness, as already mentioned.

Equation

\[ EQ\_IC2(r,t,p) \forall (p \in teg) \land (t > MIYR\_V1) \]

The portion of the cumulative cost of investment in capacity that is incurred in period t.

\[ VAR\_IC_{r,t,p} \]

The cumulative cost of investment in new capacity as of period t.

\[ VAR\_CCOST_{r,t,p} \]

The cumulative cost of investment in new capacity as of the previous period t-1.

\[ VAR\_CCOST_{r,t-1,p} \]
4.10 EQ_LA1(r,t,p,k)

**Description:** The constraint for an ETL technology that sets a lower bound on the continuous variable VAR_LAMBD(r,t,p,k).

**Purpose and Occurrence:** To set the lower bound for VAR_LAMBD(r,t,p,k) to CCAPK(r,k-1,p) * VAR_DELTA, where CCAPK(r,k-1,p) is the left hand end of the k\textsuperscript{th} interval and VAR_DELTA = VAR_DELTA(r,t,p,k) is the binary variable associated with VAR_LAMBD(r,t,p,k). If binary variable VAR_DELTA = 1, the effect is to set a lower bound on variable VAR_LAMBD(r,t,p,k) of CCAPK(r,k-1,p), whereas if VAR_DELTA = 0 the effect is to set a lower bound of 0. This constraint, in combination with other ETL constraints, is fundamental to ensuring the validity of the piecewise linear approximation of the cumulative cost curve.

This equation is generated in each time period, for which the ETL technology is available, and for each interval k in the piecewise linear approximation of the cumulative cost curve.

**Units:** Technology capacity units.

**Type:** Binding. The equation is a greater than or equal to (\(\geq\)) constraint.

**Interpretation of the results:**

*Primal:* The level of this constraint must be greater than or equal to zero in a feasible solution.

*Dual variable:* The dual variables of mixed integer problems have limited usefulness, as already mentioned.

**Equation**

\[ EQ_{-}LA1_{r,t,p,k} \forall\left( p \in \text{teg} \right) \land \left( (r, t, p) \in rtp \right) \]

- Portion of the cumulative investment in capacity that lies in the k\textsuperscript{th} interval (of the piecewise linear approximation of the cumulative cost curve), in the current period.

\[ VAR_{-}LAMBD_{r,t,p,k} \geq \]

- Left hand end of the k\textsuperscript{th} interval (CCAPK(r,k-1,p)) times binary variable VAR_DELTA(r,t,p,k), in the current period.

\[ CCAPK_{r,k-1,p} \ast VAR_{-}DELTA_{r,t,p,k} \]
4.11 EQ_LA2(r,t,p,k)

**Description:** The constraint for an ETL technology that sets an upper bound on the continuous variable VAR_LAMBD(r,t,p,k).

**Purpose and Occurrence:** To set the upper bound of VAR_LAMBD(r,t,p,k) to CCAPK(r,k,p) * VAR_DELTA, where CCAPK(r,k,p) is the right hand end of the k\textsuperscript{th} interval and VAR_DELTA = VAR_DELTA(r,t,p,k) is the binary variable associated with VAR_LAMBD(r,t,p,k). If binary variable VAR_DELTA = 1, the effect is to set an upper bound on variable VAR_LAMBD(r,t,p,k) of CCAPK(r,k,p), whereas if VAR_DELTA = 0 the effect is to set an upper bound of 0. This constraint, in combination with other ETL constraints, is fundamental to ensuring the validity of the piecewise linear approximation of the cumulative cost curve.

This equation is generated in each time period, for which the ETL technology is available, and for each interval k in the piecewise linear approximation of the cumulative cost curve.

**Units:** Technology capacity units.

**Type:** *Binding.* The equation is a less than or equal to (\(\leq\)) constraint.

**Interpretation of the results:**

*Primal:* The level of this constraint must be less than or equal to zero in a feasible solution.

*Dual variable:* The dual variable (DVR_LA2) of this constraint in the MIP solution is of little interest.

**Equation**

\[
MR\_LA2_{r,t,p,k} \forall [(p \in teg) \land ((r,t,p) \in rtp)]
\]

Portion of the cumulative investment in capacity that lies in the k\textsuperscript{th} interval (of the piecewise linear approximation of the cumulative cost curve), in the current period.

\[
VAR\_LAMBD_{r,t,p,k} \leq \{\}
\]

Right hand end of the k\textsuperscript{th} interval (CCAPK(r,k,p)) times binary variable R_DELTA(r,t,p,k), in the current period.

\[
CCAPK_{r,k,p} \ast VAR\_DELTA_{r,t,p,k}
\]
4.12  EQ_MRCLU(r,t,p)

Description: For a key learning ETL technology it defines investment in new capacity (VAR_NCAP) as the weighted sum of investments in new capacity of the attached clustered technologies in multiple regions. The weights used are the numeric values of the TL_MRCLUST parameter.

Purpose and Occurrence: Defines the relationship between investment in new capacity for a key learning ETL technology and investment in new capacity for the associated clustered technologies. This equation is generated in each time period for which the ETL technology is available. It is a key learning technology, that is, it has associated clustered technologies, possibly in multiple regions.

Units: Money units, e.g., million 2010 US$, or any other unit in which costs are tracked.

Type: Binding. The equation is an equality (=) constraint.

Interpretation of the results:
Primal: The level of this constraint must be zero in a feasible solution.
Dual variable: The dual variable of this constraint in the MIP solution is of little interest.

Remarks: Activation of the special clustered learning ETL option occurs automatically if data is included for the TL_MRCLUST parameter.

Equation

\[ \text{EQ}_-\text{MRCLU}_{r,t,p} \left[ (p \in \text{teg}) \land (\text{TL}_-\text{RP}_-\text{KC}_{r,p}) \land ((r,t,p) \in \text{rtp}) \right] \]

\[
\text{VAR}_-\text{NCAP}_{r,t,p} \overset{=}{=} \sum_{(\text{reg},t,p) \in \text{rtp}} \left( \text{TL}_-\text{MRCLUST}_{\text{reg},p,\text{prc}} \times \text{VAR}_-\text{NCAP}_{\text{reg},t,\text{prc}} \right)
\]

The weighted sum of the investments in new capacity in period t of the clustered technologies p’ attached to the key learning technology p ∈ teg, and whose START period is less than or equal to t. The weights used are the numeric values of the CLUSTER parameter.
4.13 EQ_OBJSAL(r,cur)

**Description:** Regional salvage value part of objective function adjusted to include the salvage value of endogenously determined investments (VAR_IC) in learning technologies. A salvage value for a learning technology investment exists when the technical lifetime of the investment exceeds the model horizon.

**Purpose and Ocurrence:** The objective function part calculating the salvage value is changed (for learning technologies only) by replacing the traditional calculation of the salvage value of investments with one based on the investment costs of learning technologies (VAR_IC).

**Units:** Money units, e.g., million 2000 US$, or any other unit in which costs are tracked.

**Type:** *Binding.* The equation is an equality (=) constraint.

**Equation**

\[
EQ_{-\, OBJSAL}^{r, cur}
\]

- All the basic objective function term for calculating the salvage value (section 5.2.8)

\[
\cdots
\]

The calculated salvage value associated with the ETL technologies. The internally derived parameter coefficient OBJSIC describing the portion of the investment costs that has to be salvaged. It takes into account the discounting of the salvage value.

\[
+ \sum_{t, p \in teg} \left[ OBJSIC_{r, t, p} \times VAR_{-\, IC}^{r, t, p} \right]
\]
4.14 \texttt{EQ\_OBJINV(r,cur)}

- see \texttt{EQ\_OBJINV} in section 5.2.2 for a general description without ETL

\textbf{Description:} Regional investment cost part of objective function adjusted to include the endogenously determined investment cost (VAR\_IC) for new investments in learning technologies.

\textbf{Purpose and Occurrence:} The objective function part calculating the investment costs is changed (for learning technologies only) by replacing the traditional calculation of discounted cost of investments in new capacity with that of the endogenously determined value. This equation is generated for each region where the learning investment costs occur in each time period beginning from the period, for which the ETL technology is available.

\textbf{Equation}

\begin{equation}
\texttt{EQ\_OBJINV}_{r,\text{cur}} = \sum_{t, p \in \text{teg}} \left[ \text{DISC}_{r,t,p} \cdot \text{VAR\_IC}_{r,t,p} \right]
\end{equation}

All the basic objective function terms for investment costs (section 5.2.2)

\begin{itemize}
  \item \item \item
\end{itemize}

The calculated investments costs associated with the ETL technologies.
